(54) Title: IMPROVED SECRETION OF NEUBLASTIN

(57) Abstract: The present invention concerns methods and compositions for producing a neublastin polypeptide as well as local delivery of neublastin to specific regions of the nervous system including the central nervous system and the eye for example by gene therapy. The biologically active neublastin polypeptide is produced from a construct not encoding naturally occurring neublastin pro-region, i.e. a construct comprising a nucleic acid with a promoter sequence operably linked to a nucleotide sequence encoding a signal peptide and a neublastin polypeptide, wherein said nucleotide sequence does not encode a neublastin pro-region.

**Improved secretion of neublastin**

All references cited in the present application are hereby incorporated by reference in their entirety.

5

**FIELD OF INVENTION**

The present invention concerns methods and compositions for producing a neublastin polypeptide as well as local delivery of neublastin to specific regions of the nervous system including the central nervous system and the eye for example by gene therapy. The invention includes the delivery of neublastin from transduced or trans-  
10 fected cells encapsulated into a macrocapsule with a semipermeable membrane. The invention further concerns mammalian cells capable of producing neublastin in increased amounts.

15

**BACKGROUND OF THE INVENTION**

Cells have ways to direct de novo synthesised proteins to various compartments of the cells and to the extracellular space. Signal peptides are enclosed in the coding  
20 part of the chromosomal DNA and are synthesised as part of the protein by the ribosomal apparatus. Signal peptides make up the N-terminal and cause the newly synthesised polypeptides to be directed into the rough endoplasmic reticulum. Here, the signal peptide is cleaved from the polypeptide and the mature protein is secreted into the surroundings. Thus, the signal peptide remains inside the cell.

25

The pro-part of the protein is cleaved from the mature part of the protein and ends outside the cell. For some neurotrophic factors, e.g. NGF, the pro-part of the protein is bioactive as a neuropeptide.

30 In gene therapy where the inserted gene codes for a protein which is to be secreted, a signal sequence will need to be placed in front of the mature protein to ensure its proper processing through the rough endoplasmic reticulum and the Golgi Apparatus. The first choice is almost invariably the native signal sequence of the protein in question, because it is generally desired that the protein is secreted and/or processed in  
35 the same way as it is secreted and processed by the native cell. For some uses it is also desired that the amount of protein expressed is the same as in the native cell. Furthermore, one cannot exclude the possibility that the cleaved signal sequence

plays a role in the metabolism of the cell. Finally one of skill in the art would chose to use the pre-pro-part protein to ensure correct processing and folding of the mature protein.

5 In many cases it has turned out that in vivo transduced and transfected cells which are supposed to secrete a therapeutic factor do not secrete the therapeutic factor in therapeutically sufficient quantities and for sufficient time. This may also be a problem in ex vivo gene therapy where cells are transfected or transduced outside the body and inserted into the patient after genetic modification.

10

The prior art does not provide much information concerning the coupling of signal peptide with heterologous proteins in mammals. For heterologous expression of mammalian proteins in fungi or yeast it is common practise to replace the mammalian signal peptide with one that is functional in the producer species.

15

## SUMMARY OF THE INVENTION

The present invention relates to a method for producing a biologically active neublastin polypeptide, comprising culturing a cell comprising an expression vector comprising a nucleic acid comprising a promoter sequence operably linked to a nucleotide sequence encoding a signal peptide and a neublastin polypeptide, wherein said nucleotide sequence does not encode a neublastin pro-region.

25 The native human pre pro neublastin polypeptide is 220 amino acids long (Figure 17A) (SEQ ID NO: 10). The neublastin signal peptide consists of 39 amino acids, beginning with methionine at position 1 and ending with alanine at position 39 (Figure 17B). The longest full length pro-domain of neublastin consists of 69 amino acids, beginning with serine at position 40 and ending with arginine at position 107 (Figure 17C). One mature neublastin polypeptide consists of the C terminal 113 amino acids, beginning with alanine at position 108 and ending with glycine at position 220. Pre-pro-Neublastin contains several possible pro-peptide cleavage sites and expression of pre-pro-Neublastin in mammalian cells results in secretion of a variety of mature peptides, possible forms consisting of the C-terminal 140, 113, 107, and 104 amino acids. For each of these mature forms, there is one corresponding pro-domain made up of the amino acids from position 40, to the position preceding the first residue in the mature peptide.

35

The present invention provides a solution to the problem of almost complete absence of secretion of neurotrophic factor, including neublastin, often experienced upon transduction of mammalian cells with viral vectors both in vivo and in vitro. The phenomenon is also observed for plasmid based expression vectors. For some unknown  
5 reason mammalian cells are often blocked from secreting the neurotrophic factor encoded by the vector. One possible explanation could be that correct processing of secreted proteins is cell specific. This represents a serious problem in the use of viral vector gene therapy. Today, viral vector gene therapy is considered the most preferred (if not only relevant) method for in vivo or ex vivo gene therapy because the  
10 viral vectors ensure stable integration into the genome of the transduced cell.

The invention provides for efficient expression of a mature human neublastin, or a biologically active truncation of a mature human neublastin, i.e., a secreted neublastin polypeptide, as a pre protein, instead of as a pre pro protein. A neublastin pre  
15 protein according to the invention generally comprises two components: a secreted neublastin polypeptide (as defined above), and a heterologous signal sequence.

Furthermore the present inventors have shown that by replacing the native signal peptide of neublastin with an alternative signal peptide from other proteins, such as  
20 from immunoglobulin heavy chain variable region, the secretion of neublastin is further enhanced, especially from transduced cells.

Furthermore the present inventors have shown that by removing the nucleotide sequence encoding the pro-region from the nucleotide sequence encoding the signal  
25 peptide as well as the neublastin polypeptide, then it is possible to express and have a higher amount of neublastin secreted, than if the pro-region is included.

It has been found that although the pro-region is necessary for many proteins to fold correctly, it is possible to produce a biologically active neublastin polypeptide without a pro-region.  
30

In a further aspect the invention relates to the nucleotide sequence encoding the signal peptide and the neublastin polypeptide, the expression vector comprising the nucleotide sequence, a pharmaceutical composition comprising the vector according to  
35 the invention and one or more pharmaceutically acceptable adjuvants, excipients, carriers and/or diluents. The pharmaceutical composition can be used for in vivo and ex vivo gene therapy.

In a further aspect the invention relates to an isolated host cell transduced or transfected with the vector according to the invention.

- 5 Such genetically modified host cells have turned out to produce unexpectedly high amounts of neublastin compared to cells transduced or transfected with vectors encoding neublastin with its native signal sequence. These transduced or transfected host cells therefore constitute a promising source of producer cells for the industrial scale production of neublastin. The neublastin-secreting cells can also be used for  
10 transplantation into mammalian subjects as a source of neublastin. One particular application is ex vivo gene therapy.

- In a further aspect the invention relates to a packaging cell line capable of producing an infective vector particle, said vector particle comprising a retrovirally derived genome comprising a 5' retroviral LTR, a tRNA binding site, a packaging signal, a promoter operably linked to a polynucleotide sequence encoding a fusion protein comprising neublastin and a Immunoglobulin signal peptide, an origin of second strand  
15 DNA synthesis and a 3' retroviral LTR.

- 20 These packaging cell lines can be used for producing the viral vectors according to the invention. They can also be used for in vivo gene therapy when encapsulated and transplanted to the CNS.

- In a further aspect, the invention relates to a transgenic non-human mammal comprising at least one cell being transduced or transfected with the vector according to the invention. Such animals that overexpress neublastin can be used for gene profiling and in the screening and development of drugs.  
25

- Preferably the transduced or transfected cell has the genotype of the individual animal, i.e. is not an allogenic or xenogenic transplant.  
30

- In a further aspect, the invention relates to an implantable cell culture device, the device comprising:  
a semipermeable membrane permitting the diffusion of a neurotrophic factor there-  
35 through; and  
at least one isolated host cell according to the invention.

These capsules can be used for the local delivery of neublastin upon transplantation into the central nervous system. Localised and prolonged delivery of growth factor is a preferred administration method for the treatment of a number of CNS disorders, including but not limited to Parkinson's disease, Alzheimer's disease, Huntington's disease, stroke, and amyotrophic lateral sclerosis (ALS). The capsules can likewise be used for local and prolonged delivery of neublastin for peripheral disorders including but not limited to neuropathy and neuropathic pain. Further indications include eye disorders.

10 The capsules of this invention provide for the delivery of viral particles to a desired site in a patient using a capsular approach. Encapsulation of vector-producing cell lines permits continuous delivery of the viral particle to the target site, as opposed to a single infusion. In addition, repeat therapy is possible, with reduced likelihood of immune attack. The capsules have pores large enough to allow passage of viral particles released from the packaging cells, yet prevent host-cell passage into the capsule.

This capsular approach increases the safety and control of the therapy because the devices can easily be retrieved (terminating the transduction treatment) or explanted and reimplanted (modifying the treatment). Further, the chance of infection is reduced because the capsular device is not open or externalised.

Finally, because encapsulation prevents the packaging cells from migrating within the patient, and prolongs the viability of the packaging cells upon implant, fewer cells are likely to be needed for this therapy. This may be advantageous in further lowering an immune reaction in the patient.

In a further aspect the invention relates to use of the vector according to the invention as a medicament.

30

In a still further aspect the invention relates to use of the vector according to the invention for the preparation of a medicament for the treatment of a nervous system disorder.

35 In another aspect the invention relates to the use of the vector according to the invention for the preparation of a medicament for the treatment of a CNS disorder.

Furthermore, the invention relates to a method of treating a nervous system disease, said method comprising administering to an individual in need thereof:  
a therapeutically effective amount of the vector of the invention; or  
a therapeutically effective amount of the pharmaceutical composition comprising the  
5 vector.

According to this aspect of the invention there is provided improved in vivo gene therapy methods for the treatment of nervous system diseases. As evidenced by the appended examples, transduction with the viral vectors of the present invention re-  
10 sults in hitherto unseen secretion of the encoded neublastin and as a consequence improved therapeutic effect.

In a still further aspect the invention relates to a method of treating a nervous system disease, said method comprising transplanting to an individual in need thereof:  
15 - a therapeutically effective amount of the transduced cells of the invention; or  
- an implantable device according to the invention or

This aspect provides another way of treating nervous system disorders based on ex vivo gene therapy and implantation of therapeutic cells capable of secreting in-  
20 creased amounts of neublastin.

The currently preferred method for large-scale production of neublastin is heterolo- gous expression in *E. coli*, subsequent lysis, extraction, purification, refolding and op- tionally cleavage of the protein. An alternative method which is used for production of  
25 research scale amounts includes culture of a mammalian producer cell such as CHO cells secreting correctly processed and folded neublastin into the culture medium, from where it can be isolated relatively easily. The mammalian cells of the present invention produce neublastin in higher amounts than seen before for mammalian cells and therefore represent an improved source of cells for producing bioactive  
30 neublastin, which is correctly processed and folded neublastin.

Figure 9 depicts the sequence of the 104 carboxy (C) terminal amino acids of the native human neublastin polypeptide (SEQ ID NO: 19) and the corresponding DNA sequence encoding the 104 C terminal amino acids of the native human neublastin (SEQ ID NO: 58) aligned with a synthetic gene encoding the 104 C terminal amino acids of the native human neublastin optimized for CHO cell expression (SEQ ID NO: 59). Nucleotides in the synthetic gene that have been changed from the native sequence are indicated (\*).

35 Figure 10 depicts the neublastin sequence within plasmid pNBN026-35 (SEQ ID NO: 60). Immediately upstream of the presented sequence is a "CT" dinucleotide that

contributes to a XhoI restriction site. Immediately downstream is a BamHI restriction site.

5 Figure 11 depicts the DNA (SEQ ID NO: 61) and amino acid (SEQ ID NO: 62) sequence of the 104 C terminal amino acids of neublastin fused to a synthetic signal sequence. The signal sequence is underlined.

10 Figure 12 depicts the DNA (SEQ ID NO: 63) and amino acid (SEQ ID NO: 64) sequence of the 104 C terminal amino acids of neublastin fused to a neublastin signal sequence. The signal sequence is underlined.

15 Figure 13A depicts the DNA (SEQ ID NO: 65) and amino acid (SEQ ID NO: 66) sequence of the 104 C terminal amino acids of neublastin fused to an albumin signal sequence. The signal sequence is underlined.

Figure 13B depicts the DNA (SEQ ID NO: 69) and amino acid (SEQ ID NO: 70) sequence of the 104 C terminal amino acids of neublastin fused to a modified albumin signal sequence. The signal sequence is underlined.

20 Figure 14 depicts the DNA sequence (SEQ ID NO: 67) and amino acid sequence (SEQ ID NO: 68) of the 104 C terminal amino acids of neublastin fused to a human growth hormone signal sequence. The signal sequence, which contains an intron, is underlined.

25 Figure 15 depicts mass spectrometer results of neublastin secreted from CHO cells using the albumin signal sequence (15A) or the human growth hormone signal sequence (15B)(15C). The peaks at 11,156 and 11,157 daltons correspond to a 104-amino acid neublastin C terminal fragment. The peaks at 11,084 and 11,085 daltons correspond to a 103-amino acid neublastin C terminal fragment. Figure 15A depicts  
30 deglycosylated neublastin from albumin-directed secretion. Figure 15B depicts deglycosylated neublastin from human growth hormone-directed secretion. Figure 15C depicts neublastin from human growth hormone-directed secretion. Peaks with greater masses correspond to the presence of various glycoforms.

35 Figure 16 depicts KIRA assay results demonstrating activity of recombinantly produced neublastin produced in CHO cells.

Figure 17A depicts the amino acid sequence of full-length neublastin including the mature protein, the pro-domain and the signal peptide (SEQ ID NO: 10). Figure 17B depicts the amino acid sequence of the full-length native neublastin signal peptide. Figure 17C depicts the amino acid sequence of the full-length neublastin pro-domain.

5

## DEFINITIONS

"C terminal amino acids," as used herein, means a series of contiguous amino acids in a polypeptide chain most distal from the amino (N) terminus of the polypeptide.

10

"Neublastin pro-region" means a region comprising at least amino acids corresponding to amino acids -41 to -11 of SEQ ID NO: 10, 11, 12.

15

"Preproneublastin polypeptide," (SEQ ID NO: 10) as used herein, means a polypeptide consisting of mature human neublastin, *i.e.*, the 113 C terminal amino acids of neublastin (a.a. 108 to 220 of SEQ ID NO: 10), the full length human neublastin pro-domain, *i.e.*, the 68 amino acids proximal to the N terminus of the mature neublastin (a.a. 40 to 107 of SEQ ID NO: 10), and the human neublastin signal peptide, *i.e.*, the 39 amino acids proximal to the N terminus of the neublastin pro-domain (a.a. 1 to 39 of SEQ ID NO: 10).

20

Signal peptide – eukaryotic signal peptide. A eukaryotic signal peptide is a peptide present on proteins that are destined either to be secreted or to be membrane components. It is usually N-terminal to the protein. In the present context, all signal peptides identified in SignalP (version 2.0 or preferably version 3.0) are considered a signal peptide.

25

"Functional neublastin signal peptide," as used herein, means first 39 amino acids of SEQ ID NO: 10 or any portion thereof that effects the secretion of the mature neublastin from a cell.

30

"Functional neublastin signal sequence" means a nucleic acid sequence encoding a functional neublastin signal peptide.

35

A mammalian signal peptide is a signal peptide derived from a mammalian protein secreted through the ER.

Mature human neublastin polypeptide as used herein means the C-terminal 113 amino acids of native human neublastin, i.e. amino acids 108-220 of SEQ ID No. 10

5 Mature mouse neublastin polypeptide as used herein means the C-terminal 113 amino acids of native mouse neublastin, i.e. amino acids 112-224 of SEQ ID No. 11

Mature rat neublastin polypeptide as used herein means the C-terminal 113 amino acids of native rat neublastin, i.e. amino acids 112-224 of SEQ ID No. 12

10 Neublastin polypeptide as used herein means a polypeptide comprising the C-terminal 99-140 amino acids of native human Neublastin, the C-terminal 99-144 of native rat or mouse Neublastin. More preferably a Neublastin polypeptide comprises the C-terminal 99-113 amino acids of native human neublastin, the C-terminal 99-113 amino acids of native rat neublastin, or the C-terminal 99-113 amino acids of mouse  
15 neublastin, each with up to 15 amino acid substitutions in the native sequence. In certain contexts it will be understood that "secreted neublastin polypeptide" means a polypeptide to be secreted as opposed to one that has been secreted already. The secreted neublastin polypeptide does not contain a neublastin pro-region.

20 Functional neublastin prodomain is a peptide located between the signal peptide and the mature peptide, which propeptide is cleavable from the mature peptide by furin after cleavage of the signal peptide.

Bioactivity: ability to bind when dimerised along with GFR $\alpha$ 3 to RET and induce RET  
25 dimerisation and autophosphorylation. Measured with Kira Elisa or RET L3 Elisa assays.

"Heterologous," as used when referring to a nucleic acid sequence or an amino acid sequence, means a sequence that originates from a source foreign to the particular  
30 host cell, or, if from the same host cell, is modified from its original form.

Heterologous signal peptide – a signal peptide not naturally being operatively linked to a neublastin polypeptide.

## DETAILED DESCRIPTION OF THE INVENTION

The invention relates to a method for producing a neublastin polypeptide wherein the nucleotide sequence encoding neublastin polypeptide does not encode a pro-region.

5 In the present context a pro-region comprises at least amino acids -41 to -11 of SEQ. ID. NO.: 10, 11 or 12. More preferably the pro-region comprises at least amino acids -41 to -1 of any of SEQ. ID. NO.: 10, 11 or 12. More preferably the pro-region comprises at least amino acids -41 to 10 of any of SEQ. ID. NO.: 10, 11 or 12, most preferably it comprises the pro-domain of the sequences, corresponding to amino  
10 acids -41 to 27 of SEQ ID NO: 10, or amino acids -41 to 31 of SEQ ID NO: 11, or of SEQ ID NO: 12.

**Signal peptides**

15 The expression vector according to the invention comprises a nucleic acid comprising a promoter sequence capable of culturing a cell transduced with an expression vector comprising a nucleic acid comprising a promoter sequence capable of directing expression of a nucleotide sequence encoding a signal peptide operatively linked to a neublastin polypeptide, wherein said nucleotide sequence does not encode a  
20 pro-region of a neublastin polypeptide.

During the secretion process, the signal peptide of the neublastin pre-protein is cleaved by the host cell producing the neublastin polypeptide. While the cleavage site is generally defined, a skilled artisan will appreciate that there can be variability  
25 in the signal peptide cleavage site. Accordingly, embodiments having some ambiguity with respect to the exact cleavage site are within the scope of the invention.

The signal peptide may be any functional signal peptide, such as a heterologous signal peptide, such as a mammalian signal peptide. The signal peptide may be from  
30 any suitable species, such as human, mouse, rat, monkey, pig, dog, cat, cow or horse.

The signal peptide is linked to the neublastin polypeptide, and is preferably directly fused to said neublastin polypeptide, such as the C-terminal end of the signal peptide  
35 being fused to the N-terminal end of the neublastin polypeptide.

As evidenced by the appended examples, the use of this signal peptide in general results in an improved secretion of neublastin both in vitro and in vivo. The results were reproducible both with lentivirus-transduced cells (in vivo and in vitro) and with plasmid transfected cells (in vitro). The cells produce the mature protein as a biologically active protein when the signal peptide gene is fused directly to the gene coding for the mature protein (i.e. excluding the pro part).

The inventors have discovered that not only the native neublastin signal peptide functions as a signal peptide, but also heterologous signal peptides are useful and often provide a higher yield than the native signal peptide. The heterologous signal peptide can be selected from the group consisting of a growth factor signal peptide, a hormone signal peptide, a cytokine signal peptide and an immunoglobulin signal peptide.

Thus, examples of signal peptides are signal peptides selected from the group consisting of TGF $\beta$  signal peptides, GDF signal peptides, IGF signal peptides, BMP signal peptides, Neurotrophin signal peptides, PDGF signal peptide and EGF signal peptide, signal peptides selected from a hormone signal peptide, said hormone being selected from the group consisting of growth hormone, insulin, ADH, LH, FSH, ACTH, MSH, TSH, T3, T4, and DHEA, or an interleukin signal peptide.

In one embodiment, the signal peptide is selected from the group consisting of neurturin signal peptide, GDNF signal peptide, persephin signal peptide, and NGF signal peptide.

In another embodiment, the signal peptide is selected from the group consisting of albumin signal peptide, modified albumin signal peptide, and growth hormone signal peptide, such as a signal peptide selected from the group consisting of rat albumin signal peptide, modified rat albumin signal peptide, and human growth hormone signal peptide, such as rat albumin signal peptide and human growth hormone signal peptide.

Thus, in some embodiments, the secreted neublastin polypeptide is fused to a native rat albumin signal peptide. This is exemplified by SEQ ID NO: 66. In other embodiments, the secreted neublastin polypeptide is linked to a modified rat albumin signal sequence. This is exemplified by SEQ ID NO: 70. In other embodiments, the se-

creted neublastin polypeptide is fused to a human growth hormone signal sequence. This is exemplified by SEQ ID NO: 68.

5 In yet another embodiment, the signal peptide is an immunoglobulin signal peptide, such as the immunoglobulin heavy chain signal peptide. In particular, an immunoglobulin signal peptide may be a signal peptide selected from the group consisting of mouse IgSP (SEQ ID NO 4), rat IgSP (SEQ ID NO 6), porcine IgSP (SEQ ID NO 5), simian IgSP (SEQ ID NO 2 or 3), human IgSP (SEQ ID NO 1), such as mouse IgSP (SEQ ID NO 4) or human IgSP (SEQ ID NO 1).

10

Immunoglobulin signal peptide (IgSP) is a small 19 amino acid peptide known from a large group of mammals. The sequences from human, rhesus monkey, marmoset, rat, mouse and pig are aligned in Figure 1. The percent sequence identity compared to human IgSP varies from 21 (pig) to 68 (marmoset) percent. This relatively large variation indicates that the specific sequence can be altered to a large extent without substantially changing the biological function of the signal peptide. It is also observed that there is cross species reactivity as evidenced by the appended examples. These were carried out with the mouse IgSP which was functional in rat (in vivo experiments) and in human cells (ARPE-19 cells).

20

Preferably the IgSP is of mouse or human origin because the mouse IgSP is known to be functional in mouse, rat and human beings. For use in human beings, the IgSP preferably is of human origin in order to reduce the risk of any cross species side effect.

25

In another embodiment the signal peptide is a native neublastin signal peptide such as a native human neublastin signal peptide. In this context the latter construct of native neublastin signal peptide and a neublastin polypeptide is called delta-proneublastin.

30

In yet another embodiment, the signal peptide is a synthetic signal peptide, such as the signal peptide having the amino acid sequence of AA1-AA38 of SEQ ID NO 62. (MetSerTrpAlaTrpAlaAlaCysProProCysProThrAlaLeuGlyLeuGlyGlySerAlaLeuTrpProThrLeuAlaAlaLeuAlaLeuLeuSerSerValAlaGluAla)

35

**Neublastin**

Neublastin polypeptides are proteins, which promote survival, maintain phenotypic differentiation, prevent degeneration, promote regeneration, and restore the activity of neuronal cells and tissues. Neublastin (initially described, e.g., in WO 00/01815) has alternately been referred to as "artemin" (see, e.g., WO 00/18799) and "enovin" (see, e.g., WO 00/04050).

Neublastin has been classified as a distant member of the TGF- $\beta$  superfamily (Mas-sague, et al., 1994, Trends in Cell Biology, 4: 172-178) and is a member of glial cell line-derived neurotrophic factor ligand family ("GDNF"; WO 93/06116), in the family which includes GDNF, persephin ("PSP"; Milbrandt et al., 1998, Neuron 20: 245253) and neurturin ("NTN"; WO 97/08196). The ligands of the GDNF subfamily have in common their ability to induce signalling through the RET receptor tyrosine kinase. These three ligands of the GDNF subfamily differ in their relative affinities for a family of neurotrophic receptors, the GFR[ $\alpha$ ] receptors. Neublastin acts preferably through the GFR[ $\alpha$ ]3-RET complex. Baudet et al., Development, 127, pp. 4335-44 (2000); Baloh et al., Neuron, 21, pp. 1291-1302 (1998); Airaksinen et al., Mol. Cell. Neuroscience, 13, pp. 313-325 (1999).

20

An amino acid sequence comparison of neublastin (SEQ ID NO: 10) to the GDNF subfamily members Neurturin, Persephin and GDNF is shown in Table 1. Neublastin polypeptides useful in this invention preferably hold the GDNF subfamily fingerprint, i.e. the amino acid residues underlined in Table 1.

25

\* indicates positions which have a single, fully conserved residue.

: indicates that one of the following 'strong' groups is fully conserved:

-STA, NEQK, NHQK, NDEQ, QHRK, MILV, MILF, HY, FYW.

. indicates that one of the following 'weaker' groups is fully conserved:

30 -CSA, ATV, SAG, STNK, STPA, SGND, SNDEQK, NDEQHK, NEQHRK, VLIM, HFY.

From the amino acid sequence alignment shown in Table 1, it can be seen that neublastin has seven cysteine residues at locations that are conserved within the TGF-  
[beta] superfamily. Based on this sequence alignment, neublastin was shown to be a  
35 member of the GDNF subfamily of neurotrophic factors (LGLG - FR(Y/F)CSGSC - QxCCRP - SAxxCGC, the GDNF subfamily fingerprint, underlined in Table 1).

The neublastin polypeptides useful herein may be provided in any bioactive form,  
40 including the form of pre-proteins, mature proteins, glycosylated proteins, phosphorylated proteins, truncated forms, or any other post-translationally modified protein. It is assumed that a bioactive neublastin is in the dimerized form for each NBN variant, because dimer formation is required for activity. Little to no activity is observed in a monomeric NBN polypeptide. A bioactive neublastin polypeptide includes a dimer-  
45 ized polypeptide that, in the presence of a cofactor (such as GFR[alpha]3 or RET), binds to GFR[alpha]3 or to a complex of GFR[alpha]3 and RET, induces dimerization of RET, and autophosphorylation of RET. Accordingly, a "neublastin polypeptide," as

used herein, is a polypeptide which possesses neurotrophic activity (e.g., as described in WO 00/01815).

5 The neublastin polypeptides produced by the methods of this invention display at least one biological activity of native neublastin. Biological activity for purposes of this invention can be determined by any suitable method. A biologically active neublastin polypeptide is a polypeptide that, when dimerized, can bind, along with GFR $\alpha$ 3, to RET and induce RET dimerization and autophosphorylation. (See e.g. Sanicola et al., 1997, *Proc. Natl. Acad. Sci. USA*, 94:6238). Any method of determining receptor  
10 binding and receptor autophosphorylation may be used to evaluate the biological activity the neublastin polypeptide produced by the methods of the invention. For example, the KIRA assay (ELISA) described in Example 17 can be used to assess neublastin biological activity. (See also, Sadick et al., 1996, *Anal. Biochem.*, 235(2):207).

15 Neublastin in bioactive form can also be detected using the RetL3 ELISA assay described in Example 1. Neublastin without biological function will not be detected by the RetL3 ELISA assay.

20 The following full-length sequences represent the wild type pre-pro neublastin with wild type signal peptide. Upon transduction or transfection into mammalian cells the resulting mature neublastins are only secreted in very small amounts. The native signal peptide of human, mouse and rat neublastin is represented by the first 39 amino acids.

25 --AA<sub>80</sub>-AA<sub>140</sub> of SEQ ID NO: 10 ("wild type" human prepro),  
--AA<sub>80</sub>-AA<sub>144</sub> of SEQ ID No. 11 (mouse prepro),  
--AA<sub>80</sub>-AA<sub>144</sub> of SEQ ID NO: 12 (rat prepro),

The neublastin polypeptide secreted according to the invention can vary in length.  
30 Although the mature human neublastin polypeptide normally consists of the C terminal 113 amino acids of pre pro neublastin, not all of the 113 amino acids are required to achieve useful neublastin biological activity. Amino terminal truncation is permissible. Thus, the secreted neublastin polypeptide corresponds to the C terminal 99-113 amino acids of native human neublastin, i.e., its length can be 99, 100, 101, 102,  
35 103, 104, 105, 106, 107, 108, 109, 110, 111, 112, or 113 amino acids. Selection of the exact length of the neublastin polypeptide to be secreted is a design choice, which can be made by one skilled in the art. A secreted human neublastin polypep-

ptide consisting of the C terminal 104 amino acids of native human neublastin is exemplified in the working examples provided below. In addition to varying in length, the secreted human neublastin polypeptide can vary in sequence.

5 The following "wild-type" neublastin amino acid ("aa" or "AA") sequences are exemplary of those that are useful in the methods and compositions of this invention:

--AA<sub>1</sub>-AA<sub>140</sub> of SEQ ID NO: 10 (mature 140AA; hereafter "140NBN"),

--AA<sub>25</sub>-AA<sub>140</sub> of SEQ ID NO: 10 (mature 116AA; hereafter "116NBN"),

10 --AA<sub>28</sub>-AA<sub>140</sub> of SEQ ID NO: 10 (mature 113AA (SEQ ID No. 14); hereafter "113NBN"),

--AA<sub>1</sub>-AA<sub>144</sub> of SEQ ID NO: 11 (mouse mature 144 AA),

--AA<sub>1</sub>-AA<sub>144</sub> of SEQ ID NO: 12 (rat mature--144 AA),

15 --Peptides with a C-terminal sequence set forth in AA<sub>107</sub>-AA<sub>140</sub> of SEQ ID No. 10, more preferably AA<sub>76</sub>-AA<sub>140</sub> of SEQ ID NO. 10, and which retain the 7 Cys residues characteristic of the GDNF family and of the TGF-beta super family.

In one embodiment, the preferred neublastin polypeptide contains (seven) cysteines conserved as in SEQ ID NO. 10 at positions 43,70,74,107,108,136 and 138. These seven conserved cysteine residues are known within the TGF- superfamily to form  
20 three intramonomeric disulfide bonds (contemplated, e.g., in SEQ ID No. 10 between cysteine residues 43-108, 70-136, and 74-138) and one intermonomeric disulfide bond (contemplated, e.g., in SEQ ID NO. 10 between cysteine residues 107-107), which together with the extended beta strand region constitutes the conserved structural motif for the TGF-[beta] superfamily. See, e.g., Daopin et al., Proteins  
25 1993,17: 176-192.

Preferably the neublastin polypeptide is one of the mature forms of the wild type protein. It is presently believed that the absence of the pro-region is important for high secretion levels in genetically modified mammalian cells.

30

Neublastin polypeptides useful in the present invention also include truncated forms of the full-length neublastin molecule. In such truncated molecules, one or more amino acids have been deleted from the N-terminus or the C-terminus, preferably the N-terminus. The truncated neublastin polypeptide may be obtained by providing a  
35 mature neublastin polypeptide and contacting the mature neublastin polypeptide with at least one protease under conditions sufficient to produce the truncated neublastin polypeptide. Preferably, at least one protease is an exoprotease, and contacting the

mature neublastin polypeptide results in formation of an exopeptidase neublastin polypeptide digestion product that can be further digested with a dipeptidyl peptidase. More preferably according to the present invention the protein encoded by the expression vectors is the truncated form and needs no further processing.

5

The truncated neublastin polypeptides described herein preferably include a polypeptide sequence that encompasses the seven cysteine residues conserved in the mature neublastin sequence. In certain preferred embodiments, the truncated neublastin polypeptide includes at least the 85 carboxy terminal amino acids of mature  
10 113NBN neublastin polypeptide. In more preferred embodiments the truncated neublastin polypeptide includes at least the 98 carboxy terminal amino acids of mature human 113 NBN.

One truncated form includes the 97 amino acids from the first to the last of the seven  
15 cysteine residues of mature neublastin. This corresponds to amino acids no 2 to 97 of SEQ ID No 20.

Other variants of neublastin include truncated NBN forms. Examples of these include:

20 (i) the 112AA polypeptide sequence designated herein as NBN 112, which possesses the carboxy terminal 112 amino acids of a mature neublastin polypeptide, e.g., amino acids 29-140 of SEQ ID NO. 10.

(ii) the 111 AA polypeptide sequence designated herein as NBN111, which  
25 possesses the carboxy terminal 111 amino acids of a mature neublastin polypeptide, e.g., amino acids 30-140 of SEQ ID NO. 10.

(iii) the 110 AA polypeptide sequence designated herein as NBN110, which  
30 possesses the carboxy terminal 110 amino acids of a mature neublastin polypeptide, e.g., amino acids 31-140 of SEQ ID NO. 10.

(iv) the 109 AA polypeptide sequence designated herein as NBN109, which  
35 possesses the carboxy terminal 109 amino acids of a mature neublastin polypeptide, e.g., amino acids 32-140 of SEQ ID NO. 10.

(v) the 108AA polypeptide sequence designated herein as NBN108, which possesses the carboxy terminal 108 amino acids of a mature neublastin polypeptide, e.g., amino acids 33-140 of SEQ ID NO. 10.

5 (vi) the 107AA polypeptide sequence designated herein as NBN107, which possesses the carboxy terminal 107 amino acids of a mature neublastin polypeptide, e.g., amino acids 34-140 of SEQ ID NO. 10.

10 (vi) the 106AA polypeptide sequence designated herein as NBN106, which possesses the carboxy terminal 106 amino acids of a mature neublastin polypeptide, e.g., amino acids 35-140 of SEQ ID NO. 10.

15 (viii) the 105AA polypeptide sequence designated herein as NBN105, which possesses the carboxy terminal 105 amino acids of a mature neublastin polypeptide, e.g., amino acids 36-140 of SEQ ID NO. 10.

20 (ix) the 104AA polypeptide sequence designated herein as NBN104, which possesses the carboxy terminal 104 amino acids of a mature neublastin polypeptide, e.g., amino acids 37-140 of SEQ ID NO. 10 (also set forth as SEQ ID No. 19).

(x) the 103AA polypeptide sequence designated herein as NBN103, which possesses the carboxy terminal 103 amino acids of a mature neublastin polypeptide, e.g., amino acids 38-140 of SEQ ID NO. 10.

25 (xi) the 102AA polypeptide sequence designated herein as NBN 102, which possesses the carboxy terminal 102 amino acids of a mature neublastin polypeptide, e.g., amino acids 39-140 of SEQ ID NO. 10.

30 (xii) the 101AA polypeptide sequence designated herein as NBN101, which possesses the carboxy terminal 101 amino acids of a mature neublastin polypeptide, e.g., amino acids 40-140 of SEQ ID NO. 10.

35 (xiii) the 100AA polypeptide sequence designated herein as NBN100, which possesses the carboxy terminal 100 amino acids of a mature neublastin polypeptide, e.g., amino acids 41-140 of SEQ ID NO. 10.

(xiv) the 99AA polypeptide sequence designated herein as NBN99, which possesses the carboxy terminal 99 amino acids of a mature neublastin polypeptide, e.g., amino acids 42-140 of SEQ ID NO. 10 (also set forth as SEQ ID No. 20).

- 5 It is understood that the truncated forms of neublastin disclosed herein (e.g., the 112AA through 99AA forms) have neurotrophic activity.

In most preferred embodiments, the truncated neublastin polypeptide is the 99 aa, 100 aa, 101 aa, 102 aa, 103 aa, 104 aa, 105 aa, 106 aa, 107 aa, 108 aa, 109 aa,  
10 110 aa, 111 aa or 112 aa carboxy terminal amino acids of mature 113 AA neublastin polypeptide (i. e., NBN99, NBN100, NBN101, NBN102, NBN103, NBN104, NBN105, NBN106, NBN107, NBN108, NBN109, NBN110, NBN111 or NBN112, respectively). The sequences may also be found in the mouse and rat neublastin polypeptides as the carboxy terminal 99 aa, 100 aa, 101 aa, 102 aa, 103 aa, 104 aa, 105 aa, 106 aa,  
15 107 aa, 108 aa, 109 aa, 110 aa, 111 aa or 112 aa, respectively, in SEQ ID No. 11 and 12. These most preferred examples of truncated NBN forms are bioactive (referred to "bioactive truncated neublastin polypeptides") as they have been demonstrated to have neurotrophic activity. As stated above, NBN dimerization is required for bioactivity, as little to no activity is observed with the NBN monomeric polypeptide.

20

Truncated forms of the mouse and rat neublastins are also contemplated. These may consist of the C-terminal 99, 100, 101, 102, 103, 104, 105, 106, 107, 108, 109, 110, 111, 112, 113, 114, 115, or 116 amino acids of SEQ ID No 16 (mouse) or they may consist of the C-terminal 99, 100, 101, 102, 103, 104, 105, 106, 107, 108, 109, 110,  
25 111 or 112 amino acids of SEQ ID No 18 (rat).

Thus, the invention encompasses a neublastin polypeptide selected from the group consisting of mature NBN selected from neublastin having a sequence identified as amino acids 1-140 of SEQ ID No 10, or amino acids 1-144 of SEQ ID No 11 or 12,  
30 SEQ ID No 13, 14, 15, 16, 17 or 18, N-terminally truncated NBN, mutated NBN, or mutated and N-truncated NBN, such as a mature NBN selected from the group consisting of neublastin having a sequence identified by SEQ ID No 13, 14, 15, 16, 16, 17, or 18), more particularly a neublastin polypeptide selected from the group consisting of N-terminally truncated neublastin with the 106, 104, 102 or 99 C-terminal amino acids of SEQ ID NO 10 or a neublastin polypeptide selected from the  
35 group consisting of the 116 C-terminal amino acids of human neublastin, the 113 C-terminal amino acids of human neublastin, the 104 C-terminal amino acids of human

neublastin, and the 116 C-terminal amino acids of human Neublastin, a Neublastin polypeptide having the amino acid sequence of SEQ ID No 19 or a Neublastin polypeptide containing the 99 amino acids of SEQ ID NO 20.

- 5 The NBNs useful in this invention also include those NBN polypeptides that have an amino acid sequence with substantial similarity or identity to the various prepro, pro, mature and truncated "neublastin" polypeptides set forth above. Preferably, the Neublastin polypeptide used has at least 70%, more preferably 85%, still more preferably 90%, or still further preferably 95% identity or similarity to the mature peptide
- 10 of the Neublastin polypeptides in SEQ ID NO. 10-23. Most preferably the Neublastin polypeptide used has at least 99% similarity or identity to the mature peptides of the Neublastin polypeptides in SEQ ID No. 10-23.

- The degree to which a candidate polypeptide shares homology with a Neublastin polypeptide of the invention is determined as the degree of similarity or identity between two amino acid sequences.
- 15

- A high level of sequence identity indicates likelihood that the first sequence is derived from the second sequence. Amino acid sequence identity requires identical amino acid sequences between two aligned sequences. Thus, a candidate sequence sharing 70% amino acid identity with a reference sequence, requires that, following alignment, 70% of the amino acids in the candidate sequence are identical to the corresponding amino acids in the reference sequence. Identity is determined by computer analysis, such as, without limitations, the ClustalX computer alignment program (Thompson JD, Gibson TJ, Plewniak F, Jeanmougin F, & Higgins DG: "The ClustalX windows interface: flexible strategies for multiple sequence alignment aided by quality analysis tools"; Nucleic Acids Res. 1997, 25 (24): 4876-82), and the default parameters suggested therein. Using this program, the mature part of a polypeptide encoded by an analogous DNA sequence of the invention exhibits a degree of identity of at least 70%, more preferably 85%, still more preferably 90%, or still further preferably 95%, most preferably at least 99% with the amino acid sequences presented herein as SEQ ID NO: 10 (human NBN), SEQ ID NOS: 11 and 12 (rodent NBN).
- 20
- 25
- 30

- 35 Other alignment tools are known, such as the dynamic programming algorithm described in Needleman et al., J. Mol. Biol. 48: 443 (1970), and the Align Program, a commercial software package produced by DNASTAR, Inc. the teachings of which are

incorporated by reference herein. Once the alignment between the candidate and reference sequence is made and refined, a percent homology score is calculated. The individual amino acids of each sequence are compared sequentially according to their similarity to each other.

5

Similarity factors include similar size, shape and electrical charge. One particularly preferred method of determining amino acid similarities is the PAM250 matrix described in Dayhoff et al., Atlas of protein sequence and structure 345-352 (1978 & Supp.), incorporated by reference herein. A similarity score is first calculated as the sum of the aligned pairwise amino acid similarity scores. Insertions and deletions are ignored for the purposes of percent homology and identity. Accordingly, gap penalties are not used in this calculation.

The raw score is then normalized by dividing it by the geometric mean of the scores of the candidate compound and the seven cysteine skeleton of the neublastin polypeptides. The geometric mean is the square root of the product of these scores. The normalized raw score is the percent homology.

As noted above, the neublastin polypeptides of the invention include variant polypeptides. In the context of this invention, the term "variant polypeptide" includes a polypeptide (or protein) having an amino acid sequence that differs from the mature peptide presented as part of SEQ ID NO. 10, 13, 14, 19, 20, 21, 22, or 23 (human NBN), or SEQ ID No. 11, 12, 15-18 (rodent NBN), at one or more amino acid positions. Such variant polypeptides include the modified polypeptides described above, as well as conservative substitutions, splice variants, isoforms, homologues from other species, and polymorphisms.

As defined herein, the term "conservative substitutions" denotes the replacement of an amino acid residue by another, biologically similar, residue. Typically, biological similarity, as referred to above, reflects substitutions on the wild type sequence with conserved amino acids.

Substitutes for an amino acid within the sequence of the neublastin polypeptide may be selected from other members of the class to which the amino acid belongs (see Table 1). Furthermore, various amino acids are commonly substituted with neutral amino acids, e.g., alanine, leucine, isoleucine, valine, proline, phenylalanine, tryptophan, and methionine. (See e.g. MacLennan et al., 1998, *Acta Physiol. Scand.*

*Suppl.*, 643:55-67; Sasaki et al., 1998, *Adv. Biophys.*, 35:1-24). Multiple substitutions are within the scope of the invention; however, all neublastin polypeptides of the invention must possess at least one activity of native neublastin as described infra in Section C, see also the following table:

5

Original Residues	Exemplary Substitutions
Ala (A)	Val, Leu, Ile
Arg (R)	Lys, Gln, Asn
Asn (N)	Gln
Asp (D)	Glu
Cys (C)	Ser, Ala
Gln (Q)	Asn
Gly (G)	Pro, Ala
His (H)	Asn, Gln, Lys, Arg
Ile (I)	Leu, Val, Met, Ala, Phe, Norleucine
Leu (L)	Norleucine, Ile, Val, Met, Ala, Phe
Lys (K)	Arg, 1,4-Diamino-butyric Acid, Gln, Asn
Met (M)	Leu, Phe, Ile
Phe (F)	Leu, Val, Ile, Ala, Tyr
Pro (P)	Ala
Ser (S)	Thr, Ala, Cys
Thr (T)	Ser
Trp (W)	Tyr, Phe
Tyr (Y)	Trp, Phe, Thr, Ser
Val (V)	Ile, Met, Leu, Phe, Ala, Norleucine

For example, one would expect conservative amino acid substitutions to have little or no effect on the biological activity, particularly if they represent less than 10% of the total number of residues in the polypeptide or protein. Preferably, conservative amino acid substitutions represent changes in less than 5% of the polypeptide or protein, most preferably less than 2% of the polypeptide or protein.

The neublastin polypeptide in one embodiment comprises up to 15 amino acid substitutions, such as up to 12 amino acid substitutions, such as up to 10 amino acid substitutions, such as up to 8 amino acid substitutions, such as up to 5 amino acid substitutions. For example, when calculated in accordance, e.g., with human 113NBN, most preferred conservative substitutions would represent fewer than three amino acid substitutions in the wild type mature amino acid sequence. In a particularly preferred embodiment, there is a single amino acid substitution in the mature

sequence, wherein both the substituted and replacement amino acids are non-cyclic. Other examples of particularly conservative substitutions include the substitution of one hydrophobic residue for another, such as isoleucine, valine, leucine or methionine, or the substitution of one polar residue for another, such as the substitution of arginine for lysine, glutamic for aspartic acid, or glutamine for asparagine, and the like.

The term conservative substitution also includes the use of a substituted amino acid residue in place of an un-substituted parent amino acid residue provided that antibodies raised to the substituted polypeptide also immunoreact with the un-substituted polypeptide.

Modifications of this primary amino acid sequence may result in proteins, which have substantially equivalent activity as compared to the unmodified counterpart polypeptide, and thus may be considered functional analogs of the parent proteins. Such modifications may be deliberate, e.g. as by site-directed mutagenesis, or they may occur spontaneously, and include splice variants, isoforms, homologues from other species, and polymorphisms. Such functional analogs are also contemplated according to the invention.

An alignment of 99 C-terminal amino acids from humans, mice and rats is shown below:

Substitutions are preferably conducted at positions of non-conservancy marked with "no star", ":" or ".\*".

Other preferred positions for substitution are denoted with "%".

Moreover, modifications of the primary amino acid sequence may result in proteins, which do not retain the biological activity of the parent protein, including dominant negative forms, etc. A dominant negative protein may interfere with the wild-type protein by binding to, or otherwise sequestering regulating agents, such as upstream or downstream components, that normally interact functionally with the polypeptide. Such dominant negative forms are also contemplated according to the invention.

Biologically active forms of truncated neublastin are known from WO 02/072826 (NsGene and Biogen). Truncated and mutated neublastin molecules are also known from WO 02/060929 (Biogen), especially mutated neublastin comprising an amino acid sequence derived from amino acids 8-113 of SEQ ID No. 14, wherein the variant neublastin polypeptide includes one or more of the amino acid substitutions selected from the group consisting of: an amino acid other than arginine at position 14 in the amino acid sequence of said variant polypeptide, an amino acid other than arginine at position 39 in the amino acid sequence of said variant polypeptide, an amino acid other than arginine at position 68 of said variant polypeptide, and an amino acid other than asparagine at position 95 of said variant polypeptide, for example to a lysine residue, wherein the positions of said amino acids are numbered in accordance with the polypeptide sequence of SEQ ID NO: 10. The mutated forms may be truncated as described above or include the whole length of the mature protein (amino acids 1-113 of SEQ ID NO 14). Preferably the amino acid at position 14, 39 or 68 is a lysine.

### **Cleavage of signal peptide**

Before deciding on a specific neublastin form to incorporate into an expression construct, the likelihood of cleavage of the signal peptide, such as Igsp can be checked using state of the art prediction tools. One such preferred prediction tool is the SignalP software available at the SignalP WWW server (<http://www.cbs.dtu.dk/services/SignalP-2.0/>), or preferably, the newer version 3.0 available from the same server (<http://www.cbs.dtu.dk/services/SignalP-3.0/>).

The **SignalP** WWW server will return three scores between 0 and 1 for each position in your sequence:

**C-score** (raw cleavage site score)

The output score from networks trained to recognize cleavage sites vs. other sequence positions. Trained to be:

**high** at position +1 (immediately *after* the cleavage site)

**low** at all other positions.

**S-score** (signal peptide score)

The output score from networks trained to recognize signal peptide *vs.* non-signal-peptide positions. Trained to be:

**high** at all positions before the cleavage site

**low** at 30 positions after the cleavage site and  
in the N-terminals of non-secretory proteins.

**Y-score** (combined cleavage site score)

5 The prediction of cleavage site location is optimized by observing where the C-score is high *and* the S-score changes from a high to a low value. The Y-score formalizes this by combining the height of the C-score with the slope of the S-score.

Specifically, the Y-score is a geometric average between the C-score and a smoothed derivative of the S-score (*i.e.*, the difference between the mean S-score over *d*  
10 positions before and *d* positions after the current position, where *d* varies with the chosen network ensemble).

All three scores are averages of five networks trained on different partitions of the data.

For each sequence, **SignalP** will report the maximal C-, S-, and Y-scores, and the  
15 mean S-score between the N-terminal and the predicted cleavage site. These values are used to distinguish between signal peptides and non-signal peptides. If your sequence is predicted to have a signal peptide, the cleavage site is predicted to be immediately before the position with the maximal Y-score.

For a typical **signal peptide**, the C- and Y-scores will be high at position +1, while  
20 the S-score will be high before the cleavage site and low thereafter.

For comparison the prediction can be compared to the predicted cleavage of the wildtype neublastin signal peptide (cleavage between amino acids no 39 and 40 of pre-pro NBN).

25 Preferred neublastins are those which have a predicted cleavage between the signal peptide and the neublastin in either the SignalP-NN or the SignalP-HMM program. These include but are not limited to NBN113, NBN106, NBN104, NBN102, and NBN99. Particularly preferred are neublastins which have a predicted signal peptide at this position in both SignalP-NN and SignalP-HMM. These include NBN113 and  
30 NBN99.

The newer version (3.0) also includes a new score D or Dmax (Discrimination score) that describes "signal peptidedness" that is found to correlate to level of secretion using said signal peptide with the protein in question.

- 5 It is preferred that a signal peptide used in the present invention exhibits a Dmax value of at least 0.5, such as at least 0.6, such as at least 0.7, such as at least 0.8, with the neublastin polypeptide selected.

### **Medical use and methods of treatment**

- In one aspect the invention relates to the use of the vector according to the invention  
25 for the preparation of a medicament for the treatment of a nervous system disorder. The nervous system disorder can be a disorder of the peripheral nervous system or the central nervous system.

- Neublastin is useful for treating a defect in a neuron, including without limitation le-  
30 sioned neurons and traumatized neurons. Peripheral nerves that experience trauma include, but are not limited to, nerves of the medulla or of the spinal cord. Neublastin is useful in the treatment of CNS disorders, such as a neurodegenerative disease, e.g., cerebral ischaemic neuronal damage; neuropathy, e.g., peripheral neuropathy, Alzheimer's disease, Huntington's disease, amyotrophic lateral sclerosis (ALS).  
35 Neublastin is further contemplated for use in the treatment of impaired memory, e.g., memory impairment associated with dementia.

Neublastin is also known as a therapeutic candidate for treating peripheral neuropathies, such as neuropathic pain in a mammal. The neuropathic pain may be associated with toxin-induced nerve damage, pathogen-induced nerve damage, trauma-induced nerve damage, drug-induced nerve damage, idiopathic neuropathy, diabetic neuropathy, inflammation-induced nerve damage, or neurodegeneration. Neublastin can also be used for treating peripheral neuropathy in a mammal. The peripheral neuropathy may include the group consisting of trauma-induced neuropathies, viral-induced neuropathies, chemotherapy-induced neuropathies, toxin-induced neuropathies, drug-induced neuropathies, vitamin-deficiency-induced neuropathies; idiopathic neuropathies; and diabetic neuropathies. Methods and compositions for treatment of neuropathic pain using Neublastin are disclosed in WO 02/078730 (Biogen).

Preferably, Neublastin is used for treating a disorder selected from the group consisting of peripheral neuropathy including neuropathic pain, spinal cord injury, spinal root avulsion, tic doloreaux, causalgia, corneal wounds and retinopathies.

According to one preferred embodiment of the invention the neurodegenerative disease to be treated is Parkinson's disease. Neublastin is known to increase survival of dopaminergic neurons (WO 00/01815 NsGene; Baloh et al 1998 Neuron 21:1291-1302).

The vectors, capsules, and compositions of the present invention can also be used for the treatment of eye diseases, such as retinitis pigmentosa, macular degeneration, glaucoma, and diabetic retinopathy. Neublastin may also be used in the treatment of corneal wounds and ulcers (EP 1 223 966 Biopharm).

Nervous system diseases may be treated by administering to an individual in need thereof a therapeutically effective amount of the vector of the invention; or a therapeutically effective amount of the pharmaceutical composition of the invention.

Also provided are stereotaxic coordinates for the portions of the brain to be transduced to or into which to transplant naked or encapsulated cells (Table II):

TABLE II

BRAIN REGION	MEDIAL- LATERAL DIMENSION	DORSAL- VENTRAL DIMENSION	ANTERIOR- POSTERIOR DIMENSION
Gpe	1.6 to 2.7	1.0 to -1.0	2.0 to -1.0
Gpi	0.5 to 2.0	0.5 to -0.7	0.7 to 2.0
SNr	0.5 to 1.5	-0.6 to -1.5	0.7 to -0.7
STN	0.5 to 2.0	0.0 to -1.0	0.6 to -1.0
NBM	1.5 to 2.5	0.0 to -1.2	0.5 to 1.6
Striatum:	0.5 to 2.0	1.5 to 3.0	1.5 to 3.0
caudate	1.2 to 3.3	1.5 to -1.0	2.5 to -1.2
putamen			

In the foregoing table: the medial-lateral dimensions are relative to midline of the brain; the anterior-posterior dimensions are relative to the midpoint between the anterior commissure and posterior commissure with negative indicating the posterior direction; the dorsal-ventral dimensions are relative to a line connecting the midpoints of the anterior and posterior commissures with negative being ventral to said line; all dimensions are in centimeters; and Gpe means external segment of globus pallidus; Gpi means internal segment of globus pallidus; Snr means substantia nigra pars reticulata; STN means subthalamic nucleus; NBM means nucleus basalis of meynert; and caudate means caudate nucleus.

Instead of in vivo transduction, nervous system diseases can be treated by transplanting to an individual in need thereof:

- i. a therapeutically effective amount of the transduced or transfected cells according to the invention; or
- ii. an implantable device comprising transduced or transfected cells.

Preferably the transplantation comprises cells or implantable devices.

Said transplantation may comprise an autologous transplant, an allogeneic transplant or a xenogeneic transplant.

#### Target Tissues for Treatment of Neurodegenerative Disorders in the Central Nervous system

An important parameter is the selection of a suitable target tissue. A region of the brain is selected for its retained responsiveness to neurotrophic factors. Targeting of

an area may be achieved by delivering a dosage unit of a gene therapy vector as herein described or by implanting naked or encapsulated cells according to the invention.

5 In humans, CNS neurons which retain responsiveness to neurotrophic factors into adulthood include the cholinergic basal forebrain neurons, the entorhinal cortical neurons, the thalamic neurons, the locus coeruleus neurons, the spinal sensory neurons and the spinal motor neurons.

10 An initial scan, such as an MRI scan, may be performed on the patient to determine the precise location of the treatment site. For example, in treating Parkinson's disease, the basal ganglia, including substantia nigra, are treatment sites. The affected areas of the brain will likely of a size such that selection of 5 or fewer delivery sites will be sufficient for restoration of a clinically significant number of  
15 dopaminergic neurons. The same number of delivery sites may apply outside the brain.

For in vivo gene therapy, delivery may be systemic or local. By systemic delivery is intended administration of gene therapy vector intramuscularly, subcutaneously, or  
20 intraperitoneally, which will result in continuous release of Neublentin to the circulatory system.

For in vivo gene therapy, specific in vivo gene delivery sites are selected so as to cluster in an area of neuronal or terminal loss. Such areas may be identified clinically  
25 using a number of known techniques, including magnetic resonance imaging (MRI) and biopsy. In humans, non-invasive, in vivo imaging methods such as MRI will be preferred. Once areas of neuronal or terminal loss are identified, delivery sites are selected for stereotaxic distribution so each unit dosage of Neublentin is delivered into the brain or spinal cord at, or within 500  $\mu\text{m}$  from, a targeted cell, and no more  
30 than about 10 mm from another delivery site. Within the brain, gene therapy vector may be administered to the parenchyma or the ventricles.

Within the eye, gene therapy vector may be administered to the vitreous, the subretinal space and to the sub-tenar capsule.

35 For the treatment of peripheral neuropathy including neuropathic pain, the gene therapy vector may be administered to an area of the body involved in transmission

of pain sensation. Such area may include the spinal cord and intrathecal administration.

5 In one embodiment, the vector is administered intramuscularly, subcutaneously, or intraperitoneally. In another embodiment, the vector or composition is administered to an area of the body involved in transmission of pain sensation. In a third embodiment, the vector or composition is administered intrathecally or to the spinal cord. In a fourth embodiment, the vector is administered to the brain, including the parenchyma, and the ventricles. In a fifth embodiment, the vector is administered into  
10 the eye, including the vitreous, subretinal space, and sub-tenar capsule.

### **Dosing Requirements and Delivery Protocol for in vivo gene therapy**

15 A further important parameter is the dosage of neublastin to be delivered into the target tissue. In this regard, "unit dosage" refers generally to the concentration of neublastin/ml of neublastin composition. For viral vectors, the neublastin concentration is defined by the number of viral particles/ml of neurotrophic composition. Optimally, for delivery of neublastin using a viral expression vector, each unit dosage of neublastin will comprise 2.5 to 25  $\mu$ L of a neublastin composition, wherein the  
20 composition includes a viral expression vector in a pharmaceutically acceptable fluid and provides from  $10^{10}$  up to  $10^{15}$  neublastin containing viral particles per ml of neublastin composition. Such high titers are particularly used for adeno-associated virus. For lentivirus, the titer is normally lower, such as from  $10^8$  to  $10^{10}$  transducing units per ml (TU/ml), determined as described in Example 2.

25 The neublastin composition is delivered to each delivery cell site in the target tissue by microinjection, infusion, scrape loading, electroporation or other means suitable to directly deliver the composition directly into the delivery site tissue through a surgical incision. The delivery is accomplished slowly, such as over a period of about 5-10  
30 minutes (depending on the total volume of neublastin composition to be delivered).

Those of skill in the art will appreciate that the direct delivery method employed by the invention obviates a limiting risk factor associated with in vivo gene therapy; to wit, the potential for transduction of non-targeted cells with the vector carrying the  
35 neublastin encoding transgene. In the invention, delivery is direct and the delivery sites are chosen so diffusion of secreted neublastin takes place over a controlled and

pre-determined region of the brain to optimize contact with targeted neurons, while minimizing contact with non-targeted cells.

### Gene therapy vectors

5

Broadly, gene therapy seeks to transfer new genetic material to the cells of a patient with resulting therapeutic benefit to the patient. Such benefits include treatment or prophylaxis of a broad range of diseases, disorders and other conditions.

10 Ex vivo gene therapy approaches involve modification of isolated cells, which are then infused, grafted or otherwise transplanted into the patient. See, e.g., U.S. Pat. Nos. 4,868,116, 5,399,346 and 5,460,959. In vivo gene therapy seeks to directly target host patient tissue in vivo.

15 Viruses useful as gene transfer vectors include papovavirus, adenovirus, vaccinia virus, adeno-associated virus, herpesvirus, and retroviruses. Suitable retroviruses include the group consisting of HIV, SIV, FIV, EIAV, MoMLV.

20 Preferred viruses for treatment of disorders of the nervous system are lentiviruses and adeno-associated viruses. Both types of viruses can integrate into the genome without cell divisions, and both types have been tested in pre-clinical animal studies for indications of the nervous system, in particular the central nervous system.

25 Methods for preparation of AAV are described in the art, e.g. US 5,677,158. US 6,309,634 and US 6,683,058 describe examples of delivery of AAV to the central nervous system.

30 Special and preferred types of retroviruses include the lentiviruses which can transduce a cell and integrate into its genome without cell division. Thus preferably the vector is a replication-defective lentivirus particle. Such a lentivirus particle can be produced from a lentiviral vector comprising a 5' lentiviral LTR, a tRNA binding site, a packaging signal, a promoter operably linked to a polynucleotide signal encoding said fusion protein, an origin of second strand DNA synthesis and a 3' lentiviral LTR. Methods for preparation and in vivo administration of lentivirus to neural cells are  
35 described in US 20020037281 (Methods for transducing neural cells using lentiviral vectors).

Retroviral vectors are the vectors most commonly used in human clinical trials, since they carry a 7-8 kb which is more than many other viral vectors and since they have the ability to infect cells and have their genetic material stably integrated into the host cell with high efficiency. See, e.g., WO 95/30761; WO 95/24929. Oncovirinae require  
5 at least one round of target cell proliferation for transfer and integration of exogenous nucleic acid sequences into the patient. Retroviral vectors integrate randomly into the patient's genome.

Two classes of retroviral particles have been described; ecotropic, which can infect  
10 mouse cells efficiently, and amphotropic, which can infect cells of many species. A third class includes xenotrophic retrovirus which can infect cells of another species than the species which produced the virus. Their ability to integrate only into the genome of dividing cells has made retroviruses attractive for marking cell lineages in developmental studies and for delivering therapeutic or suicide genes to cancers or  
15 tumors. These vectors may be particularly useful in the central nervous system, where there is a relative lack of cell division in adult patients.

For use in human patients, the retroviral vectors must be replication defective. This prevents further generation of infectious retroviral particles in the target tissue - instead the replication defective vector becomes a "captive" transgene stable incorporated into the target cell genome. Typically in replication defective vectors, the gag, env, and pol genes have been deleted (along with most of the rest of the viral genome). Heterologous DNA is inserted in place of the deleted viral genes. The heterologous genes may be under the control of the endogenous heterologous promoter,  
20 another heterologous promoter active in the target cell, or the retroviral 5' LTR (the viral LTR is active in diverse tissues). Typically, retroviral vectors have a transgene capacity of about 7-8 kb.

Replication defective retroviral vectors require provision of the viral proteins necessary for replication and assembly in trans, from, e.g., engineered packaging cell lines.  
30 It is important that the packaging cells do not release replication competent virus and/or helper virus. This has been achieved by expressing viral proteins from RNAs lacking the  $\psi$  signal, and expressing the gag/pol genes and the env gene from separate transcriptional units. In addition, in some packaging cell lines, the 5' LTR's have  
35 been replaced with non-viral promoters controlling expression of these genes and polyadenylation signals have been added. These designs minimize the possibility of

recombination leading to production of replication competent vectors, or helper viruses. See, e.g., U.S. Pat. No. 4,861,719 herein incorporated by reference.

The invention further relates to a nucleic acid construct comprising a nucleic acid sequence encoding a neublastin polypeptide and a signal sequence. The signal peptide and the neublastin polypeptide are as described above. Accordingly, in some embodiments, the nucleic acid construct encodes a sequence consisting of the 113 C terminal codons of the pre pro neublastin polypeptide. In certain embodiments, the nucleic acid encodes a sequence consisting of the 104 C terminal codons of the pre pro neublastin polypeptide.

The nucleic acid sequence may comprise a heterologous signal peptide, such as an albumin signal sequence, e.g., a rat albumin signal sequence, and comprises the nucleic acid sequence of SEQ ID NO: 65. In some embodiments, the nucleic acid construct encodes a modified albumin signal sequence, e.g., a rat albumin signal sequence. One exemplary embodiment is a nucleic acid construct comprising SEQ ID NO: 69. In other embodiments, the nucleic acid construct encodes a human growth hormone signal sequence. One exemplary embodiment is a nucleic acid construct comprising SEQ ID NO: 67. The human growth hormone signal sequence may comprise an intron.

In a specific embodiment of the invention, the nucleic acid construct contains a nucleic acid sequence optimized for expression in a transfected host cell. Optimization of codon usage can be advantageous by providing increased polypeptide yield, or improved efficiency of transcription or translation. One exemplary embodiment of an optimized nucleic acid construct of the invention is set forth in SEQ ID NO: 59.

Due to the known degeneracy of the genetic code, wherein more than one codon can encode the same amino acid, a DNA sequence can vary from that shown in SEQ ID NOS: 65, 67, or 69 and still encode a polypeptide having the corresponding amino acid sequence of SEQ ID NOS: 66, 68, or 70 respectively. Such variant DNA sequences can result from silent mutations (e.g. occurring during PCR amplification), or can be the product of deliberate mutagenesis of a native sequence, e.g., codon optimization.

The nucleic acid construct can be a vector. Examples of suitable plasmid vectors include but are not limited to pFRT/lac Zeo, pFRT/dhfr-1, (Invitrogen, Carlsbad, CA)

pUC, pGEM and pGEX (Pharmacia, Peapack, NJ). Other suitable vectors include viral vectors (e.g. replication defective retroviruses, adenoviruses and adeno-associated viruses), which serve equivalent functions.

## 5 Expression vectors

Expression vectors may include one or more regulatory sequences operatively linked to the nucleic acid sequence to be expressed. Examples of regulatory sequences include promoters, enhancers, and polyadenylation signals. Such regulatory sequences are described, for example, in Goeddel, 1990 *Methods Enzymol.*, 185:3. Regulatory sequences include those which direct constitutive expression of a nucleotide sequence in many types of host cells and those which direct expression of the nucleotide sequence only in certain host cells (e.g. tissue-specific regulatory sequences). It will be appreciated by those skilled in the art that the design of the expression vector will depend on such factors as the choice of the host cell to be transformed, the level of expression of protein desired, and the like. The expression vectors of the invention can be introduced into host cells to thereby produce proteins or peptides.

Construction of vectors for recombinant expression of neublastin for use in the invention may be accomplished using conventional techniques which do not require detailed explanation to one of ordinary skill in the art. For review, however, those of ordinary skill may wish to consult Maniatis et al., in *Molecular Cloning: A Laboratory Manual*, Cold Spring Harbor Laboratory (NY 1982).

Briefly, construction of recombinant expression vectors employs standard ligation techniques. For analysis to confirm correct sequences in vectors constructed, the ligation mixtures may be used to transfect/transduce a host cell and successful genetically altered cells may be selected by antibiotic resistance where appropriate.

Vectors from the transfected/transduced cells are prepared, analysed by restriction and/or sequenced by, for example, the method of Messing, et al. (*Nucleic Acids Res.*, 9: 309-, 1981), the method of Maxam, et al. (*Methods in Enzymology*, 65: 499, 1980), the Sanger dideoxy method, or other suitable methods which will be known to those skilled in the art.

Size separation of cleaved fragments is performed using conventional gel electrophoresis as described, for example, by Maniatis, et al. (Molecular Cloning, pp. 133-134, 1982).

5 Expression elements employed in the invention may vary in their strength and specificities. Depending on the host/vector system utilized, any of a number of suitable transcription and translation elements, including constitutive and inducible promoters, may be used in the expression vector. When cloning in mammalian cell systems, promoters derived from the genome of mammalian cells (e.g. metallothionein promoter) or from mammalian viruses (e.g. the CMV promoter, the adenovirus late promoter; the vaccinia virus 7.5 K promoter) may be used; when generating cell lines that contain multiple copies of expression product, SV40-, BPV- and EBV-based vectors may be used with an appropriate selectable marker.

15 Expression of a gene is controlled at the transcription, translation or post-translation levels. Transcription initiation is an early and critical event in gene expression. This depends on the promoter and enhancer sequences and is influenced by specific cellular factors that interact with these sequences. The transcriptional unit of many prokaryotic genes consists of the promoter and in some cases enhancer or regulator elements (Banerji et al., Cell 27: 299 (1981); Corden et al., Science 209: 1406 20 (1980); and Breathnach and Chambon, Ann. Rev. Biochem. 50: 349 (1981)). For retroviruses, control elements involved in the replication of the retroviral genome reside in the long terminal repeat (LTR) (Weiss et al., eds., The molecular biology of tumor viruses: RNA tumor viruses, Cold Spring Harbor Laboratory, (NY 1982)). Moloney murine leukemia virus (MLV) and Rous sarcoma virus (RSV) LTRs contain promoter and enhancer sequences (Jolly et al., Nucleic Acids Res. 11: 1855 (1983); 25 Capecchi et al., In : Enhancer and eukaryotic gene expression, Gulzman and Shenk, eds., pp. 101-102, Cold Spring Harbor Laboratories (NY 1991). Other potent promoters include those derived from cytomegalovirus (CMV) and other wild-type viral promoters. 30

Promoter and enhancer regions of a number of non-viral promoters have also been described (Schmidt et al., Nature 314: 285 (1985); Rossi and deCrombrugghe, Proc. Natl. Acad. Sci. USA 84: 5590-5594 (1987)). Methods for maintaining and increasing 35 expression of transgenes in quiescent cells include the use of promoters including collagen type I (1 and 2) (Prockop and Kivirikko, N. Eng. J. Med. 311: 376 (1984) ;

Smith and Niles, *Biochem.* 19: 1820 (1980) ; de Wet et al., *J. Biol. Chem.*, 258: 14385 (1983)), SV40 and LTR promoters.

5 In mammalian host cells, a number of viral based expression systems may be utilized. In cases where an adenovirus is used as an expression vector, a coding sequence may be ligated to an adenovirus transcription/translation control complex, e.g., the late promoter and tripartite leader sequence. This chimeric gene may then be inserted in the adenovirus genome by in vitro or in vivo recombination. Insertion in  
10 a non-essential region of the viral genome (e.g. region E1 or E3) will result in a recombinant virus that is viable and capable of expressing peptide in infected hosts (see e.g. Logan & Shenk, 1984, *Proc. Natl. Acad. Sci. USA*, 81:3655). Alternatively, the vaccinia 7.5 K promoter may be used (see, e.g., Mackett et al., 1982, *Proc. Natl. Acad. Sci. USA*, 79:7415; Mackett et al., 1984, *J. Virol.*, 49:857; Panicali et al., 1982, *Proc. Natl. Acad. Sci. USA*, 79:4927).

15

According to one embodiment of the invention, the promoter is a constitutive promoter selected from the group consisting of: ubiquitin promoter, CMV promoter, JeT promoter, SV40 promoter, and Elongation Factor 1 alpha promoter (EF1-alpha).

20 Examples of inducible/repressible promoters include: Tet-On, Tet-Off, Rapamycin-inducible promoter, Mx1.

In addition to using viral and non-viral promoters to drive transgene expression, an enhancer sequence may be used to increase the level of transgene expression. Enhancers can increase the transcriptional activity not only of their native gene but also  
25 of some foreign genes (Armelor, *Proc. Natl. Acad. Sci. USA* 70: 2702 (1973)). For example, in the present invention collagen enhancer sequences are used with the collagen promoter 2 (I) to increase transgene expression. In addition, the enhancer element found in SV40 viruses may be used to increase transgene expression. This  
30 enhancer sequence consists of a 72 base pair repeat as described by Gruss et al., *Proc. Natl. Acad. Sci. USA* 78: 943 (1981); Benoist and Chambon, *Nature* 290: 304 (1981), and Fromm and Berg, *J. Mol. Appl. Genetics*, 1: 457 (1982), all of which are incorporated by reference herein. This repeat sequence can increase the transcription of many different viral and cellular genes when it is present in series with various  
35 promoters (Moreau et al., *Nucleic Acids Res.* 9: 6047 (1981)).

Transgene expression may also be increased for long term stable expression using cytokines to modulate promoter activity. Several cytokines have been reported to modulate the expression of transgene from collagen 2 (I) and LTR promoters (Chua et al., *connective Tissue Res.*, 25: 161-170 (1990); Elias et al., *Annals N. Y. Acad. Sci.*, 580 : 233-244 (1990)); Seliger et al., *J. Immunol.* 141: 2138-2144 (1988) and Seliger et al., *J. Virology* 62: 619-621 (1988)). For example, transforming growth factor (TOF), interleukin (IL)-I, and interferon (INF) down regulate the expression of transgenes driven by various promoters such as LTR. Tumor necrosis factor (TNF) and TGF 1 up regulate, and may be used to control, expression of transgenes driven by a promoter. Other cytokines that may prove useful include basic fibroblast growth factor (bFGF) and epidermal growth factor (EGF).

Collagen promoter with the collagen enhancer sequence (Coll (E)) can also be used to increase transgene expression by suppressing further any immune response to the vector which may be generated in a treated brain notwithstanding its immune-protected status. In addition, anti-inflammatory agents including steroids, for example dexamethasone, may be administered to the treated host immediately after vector composition delivery and continued, preferably, until any cytokine-mediated inflammatory response subsides. An immunosuppression agent such as cyclosporin may also be administered to reduce the production of interferons, which downregulates LTR promoter and Coll (E) promoter-enhancer, and reduces transgene expression.

The vector may comprise further sequences such as a sequence coding for the Cre-recombinase protein, and LoxP sequences. A further way of ensuring temporary expression of the neublastin is through the use of the Cre-LoxP system which results in the excision of part of the inserted DNA sequence either upon administration of Cre-recombinase to the cells (Daewoong et al, *Nature Biotechnology* 19:929-933) or by incorporating a gene coding for the recombinase into the virus construct (Plück, *Int J Exp Path*, 77:269-278). Incorporating a gene for the recombinase in the virus construct together with the LoxP sites and a structural gene (a neublastin in the present case) often results in expression of the structural gene for a period of approximately five days.

Vectors used in methods of the invention may also include a nucleic acid sequence encoding a selectable marker that can be used to identify successfully transformed host cells. Suitable selectable markers for use in cultured mammalian cells include genes that confer resistance to drugs, such as neomycin, hygromycin, and metho-

trexate. The selectable marker may be an amplifiable selectable marker. One amplifiable selectable marker is the DHFR gene. Another suitable amplifiable marker is the DHFRr cDNA (Simonsen and Levinson, 1983, *Proc. Natl. Acad. Sci. (USA)* 80:2495). Additional selectable markers are reviewed by Thilly (*Mammalian Cell Technology*,  
5 Butterworth Publishers, Stoneham, MA). Suitable selectable markers can be chosen by any person skilled in the art. Selectable markers may be introduced into the host cell in the same vector as the neublastin pre sequence, or as part of a separate vector. The selectable marker and the neublastin sequence may be under the control of different promoters or the same promoter, the latter arrangement producing a dicis-  
10 tronic message. Constructs of this type are known in the art (see e.g. U.S. Pat. No. 4,713,339).

Expression vectors used in the methods of the invention may also encode tags that facilitate purification of the recombinantly produced neublastin polypeptide. Examples  
15 include, but are not limited to, vector pUR278 (Ruther et al., 1983, *EMBO J.*, 2:1791) in which the coding sequences of the neublastin polypeptide described herein may be ligated into the vector in frame with the lac z coding region so that a hybrid protein is produced; pGEX vectors may also be used to express the neublastin polypeptide with a glutathione S-transferase (GST) tag. These proteins are usually soluble and  
20 can easily be purified from cells by adsorption to glutathione-agarose beads followed by elution in the presence of free glutathione. The vectors include cleavage sites (thrombin or factor Xa protease or PreScission Protease™ (Pharmacia, Peapack, N.J.)) for easy removal of the tag after purification. Other fusion tags are known in the art, e.g., histidine tags, maltose binding protein tags.

25

### **Pharmaceutical preparations for gene therapy**

To form a neublastin composition for use in the invention, neublastin encoding expression viral vectors may be placed into a pharmaceutically acceptable suspension,  
30 solution or emulsion. Suitable mediums include saline and liposomal preparations.

More specifically, pharmaceutically acceptable carriers may include sterile aqueous of non-aqueous solutions, suspensions, and emulsions. Examples of nonaqueous solvents are propylene glycol, polyethylene glycol, vegetable oils such as olive oil,  
35 and injectable organic esters such as ethyl oleate. Aqueous carriers include water, alcoholic/aqueous solutions, emulsions or suspensions, including saline and buffered

media. Parenteral vehicles include sodium chloride solution, Ringer's dextrose, dextrose and sodium chloride, lactated Ringer's or fixed oils.

5 Intravenous vehicles include fluid and nutrient replenishers, electrolyte replenishers (such as those based on Ringer's dextrose), and the like.

Preservatives and other additives may also be present such as, for example, antimicrobials, antioxidants, chelating agents, and inert gases and the like. Further, a composition of neublastin transgenes may be lyophilized using means well known in the art, for subsequent reconstitution and use according to the invention.

10

A colloidal dispersion system may also be used for targeted gene delivery.

Colloidal dispersion systems include macromolecule complexes, nanocapsules, microspheres, beads, and lipid-based systems including oil-in-water emulsions, micelles, mixed micelles, and liposomes. Liposomes are artificial membrane vesicles which are useful as delivery vehicles in vitro and in vivo. It has been shown that large unilamellar vesicles (LUV), which range in size from 0.2-4.0  $\mu\text{m}$  can encapsulate a substantial percentage of an aqueous buffer containing large macro molecules. RNA, DNA and intact virions can be encapsulated within the aqueous interior and be delivered to cells in a biologically active form (Fraley, et al., Trends Biochem. Sci., 6: 77,1981). In addition to mammalian cells, liposomes have been used for delivery of operatively encoding transgenes in plant, yeast and bacterial cells. In order for a liposome to be an efficient gene transfer vehicle, the following characteristics should be present: (1) encapsulation of the genes encoding the neublastin at high efficiency while not compromising their biological activity; (2) preferential and substantial binding to a target cell in comparison to non-target cells; (3) delivery of the aqueous contents of the vesicle to the target cell cytoplasm at high efficiency; and (4) accurate and effective expression of genetic information (Mannino, et al., Biotechniques, 6: 682,1988).

15

20

25

30

The composition of the liposome is usually a combination of phospholipids, particularly high-phase-transition-temperature phospholipids, usually in combination with steroids, especially cholesterol. Other phospholipids or other lipids may also be used. The physical characteristics of liposomes depend on pH, ionic strength, and the presence of divalent cations.

35

Examples of lipids useful in liposome production include phosphatidyl compounds, such as phosphatidylglycerol, phosphatidylcholine, phosphatidylserine, phosphatidylethanolamine, sphingolipids, cerebrosides, and gangliosides. Particularly useful are diacylphosphatidylglycerols, where the lipid moiety contains from 14-18 carbon atoms, particularly from 16-18 carbon atoms, and is saturated. Illustrative phospholipids include egg phosphatidylcholine, dipalmitoylphosphatidylcholine and distearoylphosphatidylcholine.

The targeting of liposomes can be classified based on anatomical and mechanistic factors. Anatomical classification is based on the level of selectivity, for example, organ-specific, cell-specific, and organelle-specific. Mechanistic targeting can be distinguished based upon whether it is passive or active. Passive targeting utilizes the natural tendency of liposomes to distribute to cells of the reticulo-endothelial system (RES) in organs which contain sinusoidal capillaries.

Active targeting, on the other hand, involves alteration of the liposome by coupling the liposome to a specific ligand such as a monoclonal antibody, sugar, glycolipid, or protein, or by changing the composition or size of the liposome in order to achieve targeting to organs and cell types other than the naturally occurring sites of localization.

The surface of the targeted gene delivery system may be modified in a variety of ways. In the case of a liposomal targeted delivery system, lipid groups can be incorporated into the lipid bilayer of the liposome in order to maintain the targeting ligand in stable association with the liposomal bilayer. Various linking groups can be used for joining the lipid chains to the targeting ligand.

A further example of a delivery system includes transplantation into the therapeutic area of a composition of packaging cells capable of producing vector particles as described in the present invention. Methods for encapsulation and transplantation of such cells are known in the art, in particular from WO 97/44065 (Cytotherapeutics). By selecting a packaging cell line capable of producing lentiviral particles, transduction of non-dividing cells in the therapeutic area is obtained. By using retroviral particles capable of transducing only dividing cells, transduction is restricted to de-novo differentiated cells in the therapeutic area.

## Methods for Delivery of Gene Therapy Vector Composition

Following the protocol defined by the invention, direct delivery of a neublastin composition may be achieved by means familiar to those of skill in the art, including microinjection through a surgical incision (see, e.g., Capecchi, *Cell*, 22: 479-488 (1980)); electroporation (see, e.g., Andreason and Evans, *Biotechniques*, 6: 650-660 (1988)); infusion, chemical complexation with a targeting molecule or co-precipitant (e.g., liposome, calcium), and microparticle bombardment of the target tissue (Tang, et al., *Nature*, 356: 152-154 (1992)).

## Encapsulation of cells

Encapsulated cell therapy is based on the concept of isolating cells from the recipient host's immune system by surrounding the cells with a semipermeable biocompatible material before implantation within the host. The invention includes a device in which cells are encapsulated in an immunoisulatory capsule. An "immunoisulatory capsule" means that the capsule, upon implantation into a recipient host, minimizes the deleterious effects of the host's immune system on the cells in the core of the device. Cells are immunoisolated from the host by enclosing them within implantable polymeric capsules formed by a microporous membrane. This approach prevents the cell-to cell contact between host and implanted tissues, eliminating antigen recognition through direct presentation. The membranes used can also be tailored to control the diffusion of molecules, such as antibody and complement, based on their molecular weight (Lysaght et al., 56 *J. Cell Biochem.* 196 (1996), Colton, 14 *Trends Biotechnol.* 158 (1996)). Using encapsulation techniques, Cells can be transplanted into a host without immune rejection, either with or without use of immunosuppressive drugs. Useful biocompatible polymer capsules usually contain a core that contains cells, either suspended in a liquid medium or immobilized within an immobilizing matrix, and a surrounding or peripheral region of permselective matrix or membrane ("jacket") that does not contain isolated cells, that is biocompatible, and that is sufficient to protect cells in the core from detrimental immunological attack. Encapsulation hinders elements of the immune system from entering the capsule, thereby protecting the encapsulated cells from immune destruction. The semipermeable nature of the capsule membrane also permits the biologically active molecule of interest to easily diffuse from the capsule into the surrounding host tissue.

The capsule can be made from a biocompatible material. A "biocompatible material" is a material that, after implantation in a host, does not elicit a detrimental host response sufficient to result in the rejection of the capsule or to render it inoperable, for example through degradation. The biocompatible material is relatively impermeable to large molecules, such as components of the host's immune system, but is permeable to small molecules, such as insulin, growth factors, and nutrients, while allowing metabolic waste to be removed. A variety of biocompatible materials are suitable for delivery of growth factors by the composition of the invention. Numerous biocompatible materials are known, having various outer surface morphologies and other mechanical and structural characteristics. Preferably the capsule of this invention will be similar to those described by PCT International patent applications WO 92/19195 or WO 95/05452, incorporated by reference; or U.S. Pat. Nos. 5,639,275; 5,653,975; 4,892,538; 5,156,844; 5,283,187; or U.S. Pat. No. 5,550,050, incorporated by reference. Such capsules allow for the passage of metabolites, nutrients and therapeutic substances while minimizing the detrimental effects of the host immune system. Components of the biocompatible material may include a surrounding semipermeable membrane and the internal cell-supporting scaffolding. Preferably, the genetically altered cells are seeded onto the scaffolding, which is encapsulated by the permselective membrane. The filamentous cell-supporting scaffold may be made from any biocompatible material selected from the group consisting of acrylic, polyester, polyethylene, polypropylene polyacetonitrile, polyethylene terephthalate, nylon, polyamides, polyurethanes, polybutester, silk, cotton, chitin, carbon, or biocompatible metals. Also, bonded fiber structures can be used for cell implantation (U.S. Pat. No. 5,512,600, incorporated by reference). Biodegradable polymers include those comprised of poly(lactic acid) PLA, poly(lactic-coglycolic acid) PLGA, and poly(glycolic acid) PGA and their equivalents. Foam scaffolds have been used to provide surfaces onto which transplanted cells may adhere (PCT International patent application Ser. No. 98/05304, incorporated by reference). Woven mesh tubes have been used as vascular grafts (PCT International patent application WO 99/52573, incorporated by reference). Additionally, the core can be composed of an immobilizing matrix formed from a hydrogel, which stabilizes the position of the cells. A hydrogel is a 3-dimensional network of cross-linked hydrophilic polymers in the form of a gel, substantially composed of water.

Various polymers and polymer blends can be used to manufacture the surrounding semipermeable membrane, including polyacrylates (including acrylic copolymers), polyvinylidenes, polyvinyl chloride copolymers, polyurethanes, polystyrenes, poly-

amides, cellulose acetates, cellulose nitrates, polysulfones (including polyether sulfones), polyphosphazenes, polyacrylonitriles, poly(acrylonitrile/covinyl chloride), as well as derivatives, copolymers and mixtures thereof. Preferably, the surrounding semipermeable membrane is a biocompatible semipermeable hollow fiber membrane. Such membranes and methods of making them are disclosed by U.S. Pat. Nos. 5,284,761 and 5,158,881, incorporated by reference. The surrounding semipermeable membrane is formed from a polyether sulfone hollow fiber, such as those described by U.S. Pat. No. 4,976,859 or U.S. Pat. No. 4,968,733, incorporated by reference. An alternate surrounding semipermeable membrane material is poly(acrylonitrile/covinyl chloride).

The capsule can be any configuration appropriate for maintaining biological activity and providing access for delivery of the product or function, including for example, cylindrical, rectangular, disk-shaped, patch-shaped, ovoid, stellate, or spherical. Moreover, the capsule can be coiled or wrapped into a mesh-like or nested structure. If the capsule is to be retrieved after it is implanted, configurations which tend to lead to migration of the capsules from the site of implantation, such as spherical capsules small enough to travel in the recipient host's blood vessels, are not preferred. Certain shapes, such as rectangles, patches, disks, cylinders, and flat sheets offer greater structural integrity and are preferable where retrieval is desired.

When macrocapsules are used, preferably between  $10^3$  and  $10^8$  cells are encapsulated, most preferably  $10^5$  to  $10^7$  cells are encapsulated in each device. Dosage may be controlled by implanting a fewer or greater number of capsules, preferably between 1 and 10 capsules per patient.

The scaffolding may be coated with extracellular matrix (ECM) molecules. Suitable examples of extracellular matrix molecules include, for example, collagen, laminin, and fibronectin. The surface of the scaffolding may also be modified by treating with plasma irradiation to impart charge to enhance adhesion of cells.

Any suitable method of sealing the capsules may be used, including the use of polymer adhesives or crimping, knotting and heat sealing. In addition, any suitable "dry" sealing method can also be used, as described, e.g., in U.S. Pat. No. 5,653,687, incorporated by reference.

The encapsulated cell devices are implanted according to known techniques. Many implantation sites are contemplated for the devices and methods of this invention. These implantation sites include, but are not limited to, the central nervous system, including the brain, spinal cord (see, U.S. Pat. Nos. 5,106,627, 5,156,844, and 5,554,148, incorporated by reference), intrathecal implantation, and the aqueous and vitreous humors of the eye (see, PCT International patent application WO 97/34586, incorporated by reference), the subretinal space, and the sub-tenar capsule. Within the brain, the devices may be implanted in the parenchyma and the ventricles. For systemic delivery, implantation may be intramuscular, subcutaneous, or intra-peritoneal.

The ARPE-19 cell line is a superior platform cell line for encapsulated cell based delivery technology and is also useful for unencapsulated cell based delivery technology. The ARPE-19 cell line is hardy (i.e., the cell line is viable under stringent conditions, such as implantation in the central nervous system or the intra-ocular environment). ARPE-19 cells can be genetically modified to secrete a substance of therapeutic interest. ARPE-19 cells have a relatively long life span. ARPE-19 cells are of human origin. Furthermore, encapsulated ARPE-19 cells have good in vivo device viability. ARPE-19 cells can deliver an efficacious quantity of growth factor. ARPE-19 cells elicit a negligible host immune reaction. Moreover, ARPE-19 cells are non-tumorigenic.

Methods and apparatus for implantation of capsules into the CNS are described in US 5,487,739.

In one aspect the invention relates to a biocompatible capsule comprising: a core comprising living packaging cells that secrete a viral vector for infection of a target cell, wherein the viral vector is a vector according to the invention; and an external jacket surrounding said core, said jacket comprising a permeable biocompatible material, said material having a porosity selected to permit passage of retroviral vectors of 100 nm diameter thereacross, permitting release of said viral vector from said capsule.

Preferably, the core additionally comprises a matrix, the packaging cells being immobilized by the matrix. According to one embodiment, the jacket comprises a hydrogel or thermoplastic material.

Examples of suitable cells for packaging cell lines include HEK293, NIH3T3, PG13, and ARPE-19 cells. Preferred cells include PG13 and 3T3 cells.

Methods and devices for encapsulation of packaging cells are disclosed in US 6,027,721 hereby incorporated by reference in its entirety.

### Host cells

The nucleic acid constructs of the invention can be used to produce neublastin polypeptide. Eukaryotic cells may be transfected with a nucleic acid construct which encodes a recombinant neublastin polypeptide operatively linked to a heterologous signal sequence. Methods of making nucleic acid constructs and transfecting cells with the constructs are known in the art. (See e.g., Ausubel et al., eds., 1988, *Current Protocols in Molecular Biology*, Greene Publishing Associates & Wiley-Interscience: New York; Sambrook et al. 1989, *Molecular Cloning: A Laboratory Manual*, 2 ed., Cold Spring Harbor Laboratory Press: Cold Spring Harbor, NY). For example, cells can be transfected using electroporation, calcium phosphate precipitation, or infection with a viral vector. In some embodiments, the transformed host cell is a mammalian cell, e.g., a CHO cell, a COS cell, a HeLa cell, or an NIH 3T3 cell.

The transformed host cells are cultured in an appropriate growth medium and under conditions such that the secreted neublastin polypeptide is expressed and secreted from the cell. An appropriate growth medium is a medium containing nutrients required for the growth of cells. Nutrients required for cell growth may include a carbon source, a nitrogen source, essential amino acids, vitamins, minerals and growth factors. Optionally, the media can contain bovine calf serum or fetal calf serum. The growth medium can be designed to select for cells containing the nucleic acid construct. This can be done, for example, by drug selection or deficiency in an essential nutrient which is complemented by the selectable marker on the nucleic acid construct or co-transfected with the nucleic acid construct. Cultured mammalian cells are sometimes grown in commercially available serum-containing or serum-free media (e.g. MEM, DMEM)(Invitrogen, Carlsbad, CA). Factors to be considered in the selection of a medium appropriate for the particular cell line used are known in the art.

Thus, in one aspect the invention relates to isolated host cells transduced or transfected with the vector according to the invention. These cells preferably are mam-

malian host cells because these are capable of secreting and processing the encoded neublastin correctly.

5 Preferred species include the group consisting of rodent (mouse, rat), rabbit, dog, cat, pig, monkey, human being.

10 Examples of primary cultures and cell lines that are good candidates for transduction with the vectors of the present invention include the group consisting of CHO, HEK293, COS, PC12, HiB5, RN33b, neuronal cells, foetal cells, RPE cell lines, ARPE-19, human immortalised fibroblasts, C2C12, HeLa, HepG2, striatal cells, neurons, astrocytes, interneurons.

15 One preferred type of cell line for encapsulation and for naked cell therapy are retinal pigment epithelial cells (RPE cells). The source of RPE cells is by primary cell isolation from the mammalian retina. Protocols for harvesting RPE cells are well-defined (Li and Turner, 1988, Exp. Eye Res. 47:911-917; Lopez et al., 1989, Invest. Ophthalmol. Vis. Sci. 30:586-588) and considered a routine methodology. In most of the published reports of RPE cell cotransplantation, cells are derived from the rat (Li and Turner, 1988; Lopez et al., 1989). Preferably, RPE cells are derived from  
20 humans. In addition to isolated primary RPE cells, cultured human RPE cell lines may be used in the practice of the invention.

For in vivo transduction, the preferred group of host cells include striatal cells, neurons, astrocytes and interneurons. For ex vivo gene therapy, the preferred group  
25 of cells include neuronal cells, neuronal precursor cells, neuronal progenitor cells, stem cells and foetal cells. Stem cells and neuronal precursor cells have the advantage that they can integrate into the tissue and migrate. For encapsulation and for implantation of naked cells the preferred cells include retinal pigmented epithelial cells, including ARPE-19 cells; human immortalised fibroblasts; and human  
30 immortalised astrocytes. Particularly preferred are ARPE-19

In another embodiment the therapeutic cell line is selected from the group consisting of: human fibroblast cell lines, human astrocyte cell lines, human mesencephalic cell lines, and human endothelial cell lines, preferably immortalised with TERT, SV40T or  
35 vmyc.

The method for generating an immortalised human astrocyte cell lines has previously been described (Price TN, Burke JF, Mayne LV. A novel human astrocyte cell line (A735) with astrocyte-specific neurotransmitter function. *In Vitro Cell Dev Biol Anim.* 1999 May;35(5):279-88.). This protocol may be used to generate astrocyte cell lines.

5

The following three modifications of that protocol are preferably made to generate additional human astrocyte cell lines.

10

Human foetal brain tissue dissected from 5-12 weeks old fetuses may be used instead of 12-16 weeks old tissue.

The immortalisation gene *v-myc*, or TERT (telomerase) may be used instead of the *SV40 T antigen*.

Retroviral gene transfer may be used instead of transfection with plasmids.

15

The neublastin polypeptide may also be expressed in a transgenic animal, such as a rodent, cow, pig, sheep or goat. A transgenic animal is a non-human animal that has incorporated a foreign gene into its genome such that the foreign gene is passed from parent to offspring. Exogenous genes can be introduced into single-celled embryos (Brinster et al., 1985, *Proc. Natl. Acad. Sci. USA*, 82:4438). Methods of producing transgenic animals are known in the art, (Wagner et al., 1981, *Proc. Natl. Acad. Sci. USA* 78:6376; McKnight et al., 1983, *Cell* 34:335; Brinster et al., 1983, *Nature* 306:332; Ritchie et al., 1984, *Nature* 312:517; Baldassarre et al., 2003, *Theriogenology* 59:831; Robl et al., 2003, *Theriogenology* 59:107; Malassagne et al., 2003, *Xenotransplantation* 10(3):267).

25

#### **In vitro production of neublastin**

30

In a separate aspect the invention relates to mammalian cells, such as the cells defined above, capable of secreting a neublastin polypeptide in amounts in excess of 500 ng/10<sup>6</sup> cells/24 hours, more preferably in excess of 600 ng/10<sup>6</sup> cells/24 hours, more preferably in excess of 700 ng/10<sup>6</sup> cells/24 hours, more preferably in excess of 800 ng/10<sup>6</sup> cells/24 hours, more preferably in excess of 900 ng/10<sup>6</sup> cells/24 hours, such as in excess of 1000 ng/10<sup>6</sup> cells/24 hours.

35

Preferably the secreted neublastin is biologically active as determined by the RetL3 ELISA assay described in Example 1. This obviates the need for glycosylation, cleavage and re-folding.

The preferred host cells are selected from the group consisting of CHO, HEK293, COS, PC12, HiB5, RN33b, C2C12, HeLa, HepG2, and ARPE-19 cells. More preferably the group consists of CHO, HEK293, COS, and ARPE-19.

5

Neublastin or a functional equivalent thereof can be produced by culturing these cells and recovering the Neublastin from the culture medium without the need to refold or glycosylate the protein.

10 Expression can be increased even further by the inclusion of enhancer elements such as WPRE (US 6,136,597).

#### **Support matrix for Neublastin producing cells**

15 The present invention further comprises culturing Neublastin producing cells in vitro on a support matrix prior to implantation into the mammalian nervous system. The preadhesion of cells to microcarriers prior to implantation is designed to enhance the long-term viability of the transplanted cells and provide long term functional benefit.

20 To increase the long term viability of the transplanted cells, i.e., transplanted Neublastin secreting cells, the cells to be transplanted can be attached in vitro to a support matrix prior to transplantation. Materials of which the support matrix can be comprised include those materials to which cells adhere following in vitro incubation, and on which cells can grow, and which can be implanted into the mammalian body  
25 without producing a toxic reaction, or an inflammatory reaction which would destroy the implanted cells or otherwise interfere with their biological or therapeutic activity. Such materials may be synthetic or natural chemical substances, or substances having a biological origin.

30 The matrix materials include, but are not limited to, glass and other silicon oxides, polystyrene, polypropylene, polyethylene, polyvinylidene fluoride, polyurethane, poly-alginate, polysulphone, polyvinyl alcohol, acrylonitrile polymers, polyacrylamide, polycarbonate, polypentent, nylon, amylases, natural and modified gelatin and natural and codified collagen, natural and modified polysaccharides, including  
35 dextrans and celluloses (e.g., nitrocellulose), agar, and magnetite. Either resorbable or non-resorbable materials may be used. Also intended are extracellular matrix materials, which are well-known in the art. Extracellular matrix materials may be

obtained commercially or prepared by growing cells which secrete such a matrix, removing the secreting cells, and allowing the cells which are to be transplanted to interact with and adhere to the matrix. The matrix material on which the cells to be implanted grow, or with which the cells are mixed, may be an indigenous product of  
5 RPE cells. Thus, for example, the matrix material may be extracellular matrix or basement membrane material, which is produced and secreted by RPE cells to be implanted.

To improve cell adhesion, survival and function, the solid matrix may optionally be  
10 coated on its external surface with factors known in the art to promote cell adhesion, growth or survival. Such factors include cell adhesion molecules, extracellular matrix, such as, for example, fibronectin, laminin, collagen, elastin, glycosaminoglycans, or proteoglycans or growth factors.

15 Alternatively, if the solid matrix to which the implanted cells are attached is constructed of porous material, the growth- or survival promoting factor or factors may be incorporated into the matrix material, from which they would be slowly released after implantation in vivo.

20 When attached to the support according to the present invention, the cells used for transplantation are generally on the "outer surface" of the support. The support may be solid or porous. However, even in a porous support, the cells are in direct contact with the external milieu without an intervening membrane or other barrier. Thus, according to the present invention, the cells are considered to be on the "outer  
25 surface" of the support even though the surface to which they adhere may be in the form of internal folds or convolutions of the porous support material which are not at the exterior of the particle or bead itself.

The configuration of the support is preferably spherical, as in a bead, but may be  
30 cylindrical, elliptical, a flat sheet or strip, a needle or pin shape, and the like. A preferred form of support matrix is a glass bead. Another preferred bead is a polystyrene bead.

Bead sizes may range from about 10  $\mu\text{m}$  to 1 mm in diameter, preferably from about  
35 90  $\mu\text{m}$  to about 150  $\mu\text{m}$ . For a description of various microcarrier beads, see, for example, Fisher Biotech Source 87-88, Fisher Scientific Co., 1987, pp. 72-75; Sigma Cell Culture Catalog, Sigma Chemical Co., St. Louis, 1991, pp. 162-163; Ventrex

Product Catalog, Ventrex Laboratories, 1989; these references are hereby incorporated by reference. The upper limit of the bead's size may be dictated by the bead's stimulation of undesired host reactions, which may interfere with the function of the transplanted cells or cause damage to the surrounding tissue. The upper limit of the bead's size may also be dictated by the method of administration. Such limitations are readily determinable by one of skill in the art.

### Neublastin polypeptide

The invention further relates to a Neublastin polypeptide comprising a signal peptide and a Neublastin polypeptide, wherein the polypeptide lacks a Neublastin pro-region, such as a Neublastin polypeptide fused to a signal peptide. In particular, the signal peptide is linked through its C-terminal to the N-terminal of the Neublastin polypeptide through a peptide bond. The signal peptide and the Neublastin polypeptide are as defined above.

### Examples:

#### EXAMPLE 1: *In vitro* transfection with IgSP-NBN construct

##### Construction of IgSP-NBN constructs

IgSP.NBN was generated by overlap PCR. In the first amplification step, the mature fragment of NBN was amplified by PCR from the pUbi1z.NBN.BamHI vector using the primers NBNs-IgSP.Flapp (5'- GGTGAATTCGGCTGGGGGCCCCGGGCAGCC-3') and NBNas+XhoI (5'- TATACTCGAGCGAGCCCTCAGCCCAGGCA -3'). In a second PCR reaction, the IgSP sequence was amplified from the pNUT-IgSP-CNTF vector (ref. US 6,361,741) using the primers IgSPKozak1s+BamHI (5'- TATAGGATCCGCCACCATGAAATGCAGCTGGGTTATC-3') and IgSPas-NBN.Flapp (5'- GGCCCCCAGCCGAATTCACCCCTGTAGAAAG-3'). In the third step the products of step 1 and 2 were combined in a final PCR reaction that generates IgSP-NBN by using equal amounts of the two products as template with the primers IgSPKozak1s+BamHI and NBN-as+XhoI.

To generate a plasmid-based expression vector the resulting fragment was cloned in pNS1n digested with BamHI/XhoI. In this vector, the IgSP-NBN sequence is placed under transcriptional control of the CMV promoter (see Figure 3). Furthermore, the vector contains the Neo gene that confers G418 resistance when expressed in mammalian cells.

### Transient transfection studies

ARPE-19 is a human retinal pigment epithelial cell line (Dunn et al. 1996) grown in DMEM/Nutrient Mix F-12 with Glutamax (Invitrogen, Denmark) supplemented with 10% fetal bovine serum (Sigma-Aldrich, Denmark) at 37°C and 5% CO<sub>2</sub>. Cells were passaged approximately twice a week by trypsinization and reseeding (1:5 split ratio). Cells were seeded in 6-well plates (Corning Costar, Biotech Line, Denmark) at a density of 10<sup>5</sup> cells/well for transfection studies. The next day, cells were transfected with 3 µg plasmid/well in duplicate wells using Fugene6 (Roche, Germany) according to the manufacturer's specifications. NBN activity present in cell supernatants collected 3 days after transfection was assayed in a RetL3 ELISA.

### RetL3 ELISA

The RetL3 ELISA detects binding of a Ret-AP conjugate to a complex of NBN bound to the NBN-specific GFRα3 receptor. This assay will only detect NBN molecules which are functionally active. Briefly, a 96-well plate (B&W Isoplate HB, Perkin Elmer, Denmark) was coated with 100 µl 1 µg/ml Goat anti human Fc (Jackson ImmunoResearch Laboratories, TriChem, Denmark) in 50mM NaHCO<sub>3</sub> (pH=9.6) for 16 h at 4°C. After wash in PBS/0.05 % Tween20 (PBST), wells were blocked in 0.2% I-Block (Tropix, Applied Biosystems, Denmark) in PBST for 1hr at room temperature, followed by a brief wash in PBST. Cell supernatants or recombinant mouse Artemin (R&D systems, UK) were diluted in DMEM/10% FCS and subsequently incubated in the wells with 1 µg/ml GFRα3/Fc fusion protein (R&D Systems, UK) in RET-AP conditioned media (Biogen, USA) for 1.5 h at room temperature. Wells were then washed first in PBST and then in AP-buffer (200 mM Tris (pH=9.8), 10 mM MgCl<sub>2</sub>) followed by 30 min incubation with 10% Sapphire Enhancer (Tropix, Applied Biosystems, Denmark) and 2% CSPD (Tropix, Applied Biosystems, Denmark) in AP-buffer. Luminescence was determined by using Microbeta Trilux Counter (Perkin Elmer, Denmark).

### Results (Figure 4, panel (b))

NBN activities of 25.3-33.8 ng/ml were detected by using the RetL3 ELISA in supernatants collected from ARPE-19 cells transiently transfected with the pNS1n-IgSP.NBN construct. In contrast, approximately 5-fold lower NBN activity (4.4-6.4 ng/ml) is detected in ARPE-19 cells transiently transfected with a wild-type (pre-pro)NBN expression construct (pUbi1z.hNBN) included in the same experiment. Very low or undetectable NBN activity was detected in cell supernatants of ARPE-19 tran-

siently transfected with an EGFP expression construct (pNS1z-EGFP) confirming the specificity of the assay.

These results indicate that the use of a chimeric IgSP-NBN construct leads to higher release of mature NBN from mammalian cells capable of binding and activating the specific NBN receptor complex as compared to the release of NBN using a wildtype (prepro)NBN construct.

## EXAMPLE 2: *In vitro* transduction with IgSP-NBN construct

Generation of a lentiviral IgSP-NBN construct and virus stocks

To generate a lentiviral construct, pNS1n-IgSP-NBN was digested with BamHI-XhoI and the IgSP-hNBN PCR fragment (as described in example 1) was ligated into BamHI/XhoI-digested pHsCXW resulting in pHsCXW.IgSP.NBNw (Figure 3). pHsCXW is a derivative of a self-inactivating lentiviral transfer construct, pHR'-SIN<sub>18</sub> including a WPRE element (Dull et al., J.Virol., **72**(11):8463-71(1998); Zufferey et al., J.Virol., **72**(12):9873-80(1998); Zufferey et al. J.virol., **73** (4):2886-92 (1999)) generated by replacing the large non-viral part of the transfer construct with the pUC19 backbone. The sequence of pHsCXW can be accessed through GenBank ID: AY468486.

Replication-defective LV-sC.IgSP.NBN.W virus particles are generated by co-transfection of pHsC.IgSP.NBN.W with pMD.G (VSV-G pseudo-typing vector) and pBR8.91 (packaging vector) (Zufferey et al., Nat. Biotech., **15**:871-75(1997)) into 293T cells providing the required viral proteins in *trans*. Briefly, 293T cells cultured in DMEM with 4.5 g/l glucose and glutamax (Life Technologies, 32430-027) supplemented with 10 % FCS (Life Technologies, 10099-141) are seeded in T75 flasks (2x10<sup>6</sup> cells /flask) the day before transfection. For each T75 flask cells are transfected with 5 µg pMD.G, 15 µg pBR8.91 and 20 µg of transfer vector using Lipofectamine+ following the manufacturer's instructions. Virus containing cell supernatant is collected 2-3 days after the transfection, filter-sterilized through a 0.45 µm cellulose acetate or polysulphonic filter and concentrated by ultracentrifugation at 50,000xg for 90 min. at 4°C. After a second round of ultracentrifugation, the concentrated virus pellet is resuspended in DMEM, aliquoted and stored at -80°C. To determine virus titer, reverse transcriptase (RT) activity is assayed (Cepko and Pear, Current Protocols in Molecular Biology, 9.13.5-6, supplement 36) and transducing units (TU)/ml

calculated from the determined RT activity using an EGFP lentivirus with known transducing activity as reference.

#### Transduction studies

- 5 ARPE-19 cells were transduced with NBN expression vectors. Briefly, cells were seeded in 6-well plates (Corning Costar, Biotech Line, Denmark) at a density of  $10^5$  cells/well. The next day,  $2 \times 10^5$  TU of virus was added pr. well (duplicates) together with 5  $\mu\text{g/ml}$  polybrene for 4 h. The medium was changed and cultures were incubated for 3 days. Then cell supernatants were collected for RetL3 ELISA as described in Example 2.
- 10

#### *Results (Figure 4, panel (c)).*

- NBN activities of 39 ng/ml were detected by using the RetL3 ELISA in supernatants collected from ARPE-19 cells transduced with the LV-sC.IgSP.NBN.W virus. In contrast, very low or undetectable NBN activity was detected in ARPE-19 cells transduced with a lenti-virus containing the wild-type (prepro)NBN cDNA (LV-sC-NBN.W) or a control EGFP lenti-virus (LV-sCEW).
- 15

- These results indicate that, in contrast to a viral construct containing the wild type (prepro)NBN cDNA, the use of a chimeric IgSP-NBN viral construct allows high release of mature NBN from mammalian cells capable of binding and activating the specific NBN receptor complex.
- 20

#### **EXAMPLE 3: Analysis of NBN protein expressed from IgSP-NBN constructs**

25

#### Western blot analysis of cell supernatants

- NBN present in cell supernatants from transfected or transduced cell cultures was concentrated by affinity binding to GFR $\alpha$ 3-Ig prior to Western blot analysis. Briefly, 4 wells of a Nunc MaxiSorp plate were coated with 300  $\mu\text{l}$  Goat anti human Fc 1  $\mu\text{g/ml}$  (Jackson Immunoresearch Laboratories, TriChem, Denmark) in 50mM NaHCO<sub>3</sub> (pH=9.6) for 16 h at 4°C. The wells were blocked with 400  $\mu\text{l}$  1 % BSA in PBS for 1h at room temperature, followed by 3 washes in PBST. 300  $\mu\text{l/well}$  GFR $\alpha$ 3/Fc fusion protein 1  $\mu\text{g/ml}$  (R&D Systems, UK) was then added and the plate was incubated for 1 h at room temperature to maximise binding. The wells were then emptied and washed again 3 times with PBST. 300  $\mu\text{l}$  supernatant collected from transfected or transduced cell cultures was then added to each of the 4 wells and incubated for at
- 30
- 35

least 3 h with gently shaking at room temperature. The wells were then washed twice in PBST. 20  $\mu$ l of non-reducing sample buffer (2% SDS, 0.4 M Tris (pH=8.0)) was added to the first well and the plate shaken rapidly for 5 min. to elute the bound proteins. The content was transferred to the next well and the procedure was repeated  
5 to elute the proteins bound in the remaining wells. After addition of DTT to 10 mM, the samples were heated to 96°C for 5 minutes and analysed by SDS PAGE on a 15 % polyacrylamide gel using the MultiPhor II system according to the manufacturer's recommendations (Amersham Pharmacia, Denmark). The proteins were then blotted to PVDF membranes (BioRad, Denmark) that was immunostained using a  
10 rabbit polyclonal anti-NBN antibody (#378) as detecting antibody. Membranes were developed using the ECL+ system (Amersham Pharmacia, Denmark) and subjected to film exposure.

### Results

15 The #378 is a rabbit polyclonal antibody raised against an NBN-derived peptide (ALRPPPGSRPVSQPC). As seen in Figure 5 panel (a) a single band of a molecular weight between 7.2 and 18.5 kDa is recognized in reduced (+DTT) samples containing purified rat recombinant NBN produced in *E. coli* corresponding to the monomeric unglycosylated NBN113. A band of the same MW in addition to several additional  
20 bands are recognized in reduced samples from stable CHO-NBN clones established by transfection with wt(prepro)NBN. The identities of a number of these bands have been determined in previous studies using deglycosylation and N-terminal sequencing. A band with slightly lower molecular weight represents a smaller and unglycosylated version of mature NBN (NBN104). In addition a very broad band with an apparent  
25 MW of approximately 21 kDa represent glycosylated versions of NBN113 and NBN104. Bands of higher MW represent (glycosylated) pro-NBN seen occasionally in GFR $\alpha$ 3-affinity purified samples.

As seen in Figure 5 panel b, the double band of MW between 6.4 and 21.3 kDa corresponding to unglycosylated NBN113 and NBN104 is detected in two stable clones  
30 of CHO-NBN cells. The same double band is also detected in ARPE-19 transduced or transfected with IgSP-NBN expression constructs. Furthermore, a double band of MW close to 21 kDa corresponding to glycosylated NBN113 and NBN104 is seen in all samples analysed. These results indicate that processing and posttranslational  
35 modification are similar when expressed from wt(prepro)NBN and IgSP-NBN constructs.

10 **EXAMPLE 6: Cloning of deltapro-NBN into pHsCXW:**

Deltapro-NBN (SEQ. ID. NO: 82) was generated by overlap PCR in three amplification steps: 1) The relatively long 117 bp leader sequence (i.e. 39 a.a. signal peptide) of preproNBN with 5' BamHI/Kozak overhang and 10 base 3' overlap to mature NBN (143 bp); 2) mature NBN with 5' 10 base NBN leader sequence overlap and 3' XhoI (362 bp); 3) the products of steps 1 and 2 were combined in a final PCR reaction that generated Δpro-NBN (492 bp).

The first PCR reaction (NBN leader):

20 Primers used:

BamHI+Kozak+hNBNsp, 5'-TATAGGATCCGCCACCATGGAACTTGGACTTG-GAGG-3'

hNBNsp3'-matNBN FLAP as, 5'-GGCCCCCAGCGGCCTCTGCGACGCTGCTCA-3'

Plasmid pHsC.hNBN.W (see plasmid map in Fig. 7a) was used as template for the

5 PCR reaction, which was run using Pfu-turbo polymerase.

PCR conditions:

94 °C 3 min

94 °C 30 s

55 °C 30 s 35 cycles

10 72 °C 1 min

72 °C 5 min

The second PCR reaction (matureNBN):

Primers used:

15 hNBNsp3' FLAP-matNBN s, 5'-CGCAGAGGCCGCTGGGGGGCCCGGGCAGC-3'

NBNas+XhoI, 5'-TATACTCGAGCGAGCCCTCAGCCCAGGCA-3'

Plasmid pHsC.hNBN.W (see plasmid map Fig. 7a) was used as template for the

PCR reaction, which was run using Pfu-turbo polymerase.

PCR conditions:

20 94 °C 3 min

94 °C 30 s

65 °C 30 s 35 cycles

72 °C 1 min

72 °C 5 min

25

The third PCR reaction (deltapro-NBN):

Primers used:

BamHI+Kozak+hNBNsp,

5'-TATAGGATCCGCCACCATGGAACTTGGACTTGGAGG-3'

30 NBNas+XhoI, 5'-TATACTCGAGCGAGCCCTCAGCCCAGGCA-3'

The PCR fragments from the two first PCR reactions (NBN leader and mature NBN both at a 1:10 dilution were used as template for the third PCR reaction, which was run using Pfu-turbo polymerase, and the same PCR profile as the first PCR run.

35 The PCR fragment from the third PCR reaction was cut with BamHI and XhoI and cloned between BamHI and XhoI sites in pHsCXW (see plasmid map in Fig. 7b).

**EXAMPLE 7: *In vitro* transfection with IgSP-NBN constructs and deltaproNBN constructs in different cell lines**

Secretion of NBN after transient transfection with different NBN constructs, including wt pre-pro NBN, delta-pro NBN and IgSP-NBN, was compared. Transient transfections were performed in ARPE-19, HEK293, CHO and HiB5 cells.

Cell lines

ARPE-19 cells were cultured as described in example 1. HiB5 (Renfranz et al. 1991), HEK293 and CHO cells were grown in DMEM (Invitrogen, Denmark) with 10% fetal bovine serum (Invitrogen, Denmark), and medium for CHO cells were further supplemented with 20 mg/l L-proline. ARPE-19, HEK293 and CHO cells were grown at 37°C and HiB5 cells at 33°C in 5% CO<sub>2</sub>. Cells were passaged approximately twice a week by trypsinization and reseeded (1:5 split ratio).

NBN secretion after transient transfection

Cells were seeded in 6-well plates (Corning Costar, Biotech Line, Denmark) at a density of approximately 10<sup>5</sup> cells/well. The next day, cells were transfected with pHsC.hNBN.W, pHsC.IgSP.hNBN.W and pHsC.deltapro-hNBN.W, respectively. ARPE-19 cells were transfected in triplicate wells using Fugene6 as described in example 1, whereas the other three cell lines were transfected using 2 µg plasmid/well in triplicate wells using Lipofectamine Plus (Invitrogen, Denmark) according to the manufacturer's instructions. The next day, fresh growth medium was added to the wells, and cells were incubated for further 24 hours before collecting conditioned medium. Sufficient transfection efficiency was ensured by evaluation of EGFP expression in wells transfected in parallel with pHsC.EGFP.W. NBN binding activity in conditioned medium was measured using the RetL3 ELISA, as described in example 1. The RetL3 ELISA detects binding of a Ret-AP conjugate to a complex of NBN bound to the NBN-specific GFRα3 receptor. Values were calculated as ng NBN/ml/24 h and ng NBN/10<sup>5</sup> cells/24 h and adjusted to relative NBN release with values from cells transfected with the wt NBN construct set to 1. Data in figure 8 represent these three calculations and are expressed as mean ± SEM (n=3). In panel A, \* indicates a significant difference from cells transfected with the wt NBN construct (P<0.05, one way ANOVA, Fisher LSD Method)

### Results

As shown in the table below and figure 8A, the four tested cell lines showed increased NBN release when using the delpapro-NBN construct, compared to the wt NBN construct (9-17 fold higher NBN release, depending on cell line). When transfecting the four cell lines with the pHsC.IgSP.hNBN construct, NBN secretion was further enhanced (28-91 fold higher NBN release compared to wt NBN). Very low or undetectable NBN activity was seen in cell supernatants from ARPE-19 transiently transfected with the EGFP expression construct (pHs.C.EGFP.W) confirming the specificity of the assay.

	HEK293		ARPE-19		HiB5		CHO	
Construct	Mean	S.E.M.	Mean	S.E.M.	Mean	S.E.M.	Mean	S.E.M.
NBN	1,0	0,2	1,0	0,3	1,0	0,2	1,0	0,1
IgSP-NBN	28,0	4,7	48,6	12,9	42,7	5,4	91,2	15,1
dpro-NBN	12,4	0,6	17,2	5,5	13,1	1,0	9,2	0,5

Panel B in Fig. 8B shows NBN concentrations in conditioned medium (24 h) from the transiently transfected cell lines. The highest concentration ( $1240 \pm 54$  ng NBN/ml) was found in conditioned medium from HEK293 cells transfected with the IgSP-NBN construct. Panel C in Fig 8C shows NBN release per  $10^5$  cells per 24 h. IgSP-NBN transfected ARPE-19 cells showed the highest NBN release ( $133 \pm 35$  ng/ $10^5$  cells/24 h).

The present results indicate that the use of a chimeric IgSP-NBN construct and of delpapro NBN construct in order to increase secretion of mature NBN from mammalian cells is applicable in different cell types.

### EXAMPLE 8: Prediction using SignalP 3.0

Prediction of positions for signal peptides using version 3.0. The predictions were carried out on delpapro NBNs and IgSP-NBNs of the following sequences.

### Example 9: Neublastin Gene Sequence Optimization

The sequence of the native human neublastin gene was examined for codon usage for optimizing expression of human neublastin in CHO cells. The codons most commonly used in CHO cells were analyzed based on data current to 2002 using a method known in the art (Nakamura et al., 1999, *Nucleic Acids Res.*, 27(1):292). The codon usage for *Cricetulus griseus* relied upon is presented in the Table below.

**Table.** Frequency of codon usage in *Cricetulus* normalized per 1,000 codons.

The native human nucleotide sequence encoding a C terminal 104 amino acid fragment (Roseblad et al., 2000, *Mol. Cell Neurosci.* 15(2):199; Baloh et al., *Neuron* 21:1291) and the nucleotide sequence of the synthetic gene are aligned in Figure 9 with the changed nucleotides indicated. The two sequences are 83.33% identical.

### Example 10: Cloning of the Neublastin Gene

A 100 codon (300 nucleotides) 3' form of the neublastin gene was synthesized and cloned into an expression plasmid to facilitate the insertion of various signal peptide sequences linked to the 5' codons of neublastin. The 100 codon-form of the neublastin gene was assembled by combining 40 pmol of oligonucleotides KD3-464

through KD3-469 (Table 2) in 200  $\mu$ L buffer (10 mM KCl, 10 mM  $(\text{NH}_4)_2\text{SO}_4$ , 20 mM Tris-Cl, 2 mM  $\text{MgSO}_4$ , 0.1% Triton X-100, pH 8.8) containing Deep Vent Polymerase (New England BioLabs, Beverly, MA). The contents were heated to 95°C for 4 minutes and cycled twenty times as follows: 95°C for 1 minute, 60°C for 30  
5 seconds, and 72°C for 1 minute, followed by an extension at 72°C for four minutes. The termini were prepared by sequential digestion with Sall and NheI. The 330 base pair fragment, which included a non-coding region of 30 base pairs flanking the neublastin gene, was gel-purified and ligated into plasmid pFRT/dhfr-1 (a derivative of pcDNA/FRT (Invitrogen, Carlsbad, CA) with the hygromycin gene replaced by a  
10 dihydrofolate reductase gene) that had been gel-purified and digested with NheI and XhoI. The resulting plasmid was named pNBN026-35. The neublastin sequence within pNBN026-35 is presented in Figure 10.

The Table below identifies the oligonucleotides used in PCR and synthetic sequence assembly to generate signal peptide-neublastin fusion genes. Sequences  
15 are all indicated in the 5' to 3' orientation.

**Example 11: Construction of Signal Peptide-Neublastin Fusion**

Sequences encoding four different signal peptides were tested. These included signal sequences from neublastin, rat albumin, and human growth hormone. Additionally, a synthetic signal sequence resulted from two frame-shift mutations during PCR amplification to generate the neublastin signal peptide. The fusions were synthesized using either oligonucleotide assembly or PCR. The DNA fragments were ligated into pNBN026. The relevant DNA sequence of each of the four molecules described was confirmed by DNA sequence analysis.

10

The synthetic signal sequence was synthesized by PCR amplification using oligonucleotides KD3-487, KD3-479, KD3-480, KD3-481, and KD3-482 (Table) and puReTaq polymerase (Pharmacia, Peapack, NJ.). PCR conditions included heating the reaction to 95°C for 4 minutes and then cycling twenty times at 95°C for 1 minute, 60°C for 30 seconds, 72°C for 1 minute, followed by an extension at 72°C for four minutes. The termini were prepared by digestion with PstI and XhoI. The 330 base pair fragment was gel-purified and ligated into plasmid pNBN026 that was also gel-purified and digested with PstI- and XhoI. The resulting plasmid was named pNBN030. There were two spontaneous frameshift mutations not predicted or encoded by the oligonucleotides which compensated for each other and kept the translated protein in frame. The DNA and protein sequences are shown in Figure 11.

20

The neublastin signal sequence was synthesized by PCR amplification with oligonucleotides KD3-513 and KD3-514 (Table). The polymerase used was puReTaq (Pharmacia, Peapack, NJ.). PCR conditions included heating to 95°C for 4 minutes and cycling three times at 95°C for 1 minute, 60°C for 30 seconds, 72°C for 1 minute, followed by an extension at 72°C for four minutes. The termini were prepared by digestion with NheI and XhoI. The 330 base pair fragment was gel-purified and ligated into plasmid pNBN030 that was gel-purified and digested with NheI and XhoI. The resulting plasmid was named pNBN038. The DNA and protein sequences are shown in Figure 12.

25

30

The albumin signal sequence was synthesized by PCR amplification with oligonucleotides KD3-487, KD3-471, and KD3-472 (Table). The polymerase used was

35

puReTaq (Pharmacia, Peapack, NJ). PCR conditions included heating to 95°C for 4 minutes and cycling twenty times at 95°C for 1 minute, 60°C for 30 seconds, 72°C for 1 minute, followed by an extension at 72°C for four minutes. The termini were prepared by digestion with PstI and XhoI. The 330 base pair fragment was gel-purified and ligated into plasmid pNBN026 that was gel-purified and digested with PstI and XhoI. The resulting plasmid was named pNBN029. The DNA and protein sequences are shown in Figure 13.

The human growth hormone signal sequence was synthesized by PCR amplification from plasmid pV30 (a pUC-based plasmid containing the genomic copy of the 5' end of the human growth hormone gene) with oligonucleotides KD3-487, KD3-477, and KD3-485 (Table 2). The polymerase used was puReTaq (Pharmacia, Peapack, NJ). PCR conditions included heating to 95°C for 4 minutes and cycling twenty times at 95°C for 1 minute, 60°C for 30 seconds, 72°C for 1 minute, followed by an extension at 72°C for four minutes. The termini were prepared by digestion with PstI and XhoI. The 330 base pair fragment was gel-purified and ligated into plasmid pNBN026 that was gel-purified and digested with PstI and XhoI. The resulting plasmid was named pNBN031. The DNA and protein sequences are shown in Figure 14.

## **Example 12: CHO Cell Transfections**

CHO-DG44 cells were previously transformed with DNA sequences containing the Flp Recombination Target (frt) (A1 cells). This A1 host cell line does not contain the dihydrofolate reductase gene (DHFR) and is thus DHFR-minus. Each of the plasmids described encodes the DHFR gene, the neublastin fusion gene, plus the frt site. Plasmid pOG44 encodes the Flp recombinase gene. Cotransfection of these plasmids into A1 cells resulted in the insertion of a single copy of the signal-peptide-neublastin fusion genes and DHFR into the chromosome. A1 cells were electroporated with the plasmid of interest plus plasmid pOG44 under conditions consistent with those described by the manufacturer (*i.e.* 0.4 mm cuvette, 280 volts, 950 microFarads)(BioRad, Hercules, California). Transformed cells expressing DHFR were selected for their ability to grow in alpha-minus medium Minimal Essential Medium-Alpha without nucleosides (Invitrogen, Carlsbad, CA) supplemented with 10% dialyzed fetal bovine serum (Hyclone, Logan, UT). Approximately two weeks

later, colonies were isolated and expanded into larger vessels in the same selection medium. Cell cultures were transitioned to serum-free medium and analyzed.

### **Example 13: Analysis of Transfected Cell Lines**

5

Cell line candidates were screened for their ability to express neublastin. Aliquots of suspension cell cultures were centrifuged to separate cells from conditioned medium. The conditioned medium was removed from the cell pellet and both the media and the cell pellet were processed for reduced and denaturing electrophoresis on 16% polyacrylamide gels as generally described (Ausubel et al., supra). Upon completion of electrophoresis, the proteins were electroblotted onto a PVDF membrane and probed with rabbit polyclonal antiserum raised against neublastin. The antibody-Neublastin complex was detected by using a goat anti-rabbit polyclonal antiserum conjugated with horseradish-peroxidase (BioRad, Hercules, California).

15

Protein expressed from plasmids encoding the neublastin, synthetic, albumin, and human growth hormone signal peptides each expressed immuno-reactive neublastin in the cell pellet fractions. Only the albumin and human growth hormone signal peptides, however, expressed detectable levels of neublastin in conditioned medium. The electrophoretic mobility of all expressed neublastin polypeptides was consistent with an 11 kD, 104-amino acid form of neublastin.

20

### **Example 14: Sequence of Neublastin Produced in CHO cells**

25

Neublastin was purified from conditioned medium using an immunoaffinity column, generally as described (Ausubel et al., supra). The amino-terminal sequence was determined from protein purified from cell lines containing the albumin and growth hormone signal peptides. Neublastin was applied onto a micro TFA filter (Applied Biosystems, Foster City, CA) and subjected to automated Edman degradation chemistry. Amino terminal sequencing was performed on an ABI Procise 494 sequencer. The resulting PTH amino acids were separated using an ABI 140C Micro-gradient system equipped with a PTH C18 reverse-phase column and analyzed using an ABI 7785A absorbance detector. For both constructs, the primary protein sequence began with the first residue of 104-amino acid C terminal fragment of full-

30

35

length neublastin (*i.e.* alanine). The neublastin preparation expressed with the growth hormone signal peptide also included a 103-amino acid neublastin C terminal fragment lacking the amino-terminal alanine residue. The 103 amino acid form of neublastin began with an alanine. In both cases, the signal peptide  
5 functioned as anticipated, *i.e.*, the neublastin polypeptide was secreted from the cell and the signal peptide was cleaved by the cell.

#### **Example 15: Mass Spectrometry of Recombinant Neublastin**

10 Purified neublastin from conditioned medium of the cell lines containing constructs encoding the albumin and growth hormone signal peptides was analyzed by intact mass spectroscopy on a ZMD mass spectrometer (Waters, Milford, MA) as described generally by the manufacturer. For both constructs, the primary peak of de-glycosylated samples corresponded to a 104-amino acid neublastin polypeptide  
15 (Figure 15). These two signal peptides functioned as anticipated, *i.e.*, the neublastin polypeptide was secreted from the cell and the signal peptide was cleaved by the cell. Additionally, the glycosylated neublastin secreted from cells transfected with constructs encoding neublastin and growth hormone signal peptide contained various glycoforms.

20

#### **Example 16: Detection of Neublastin Activity in Media From CHO Cells Transfected With Constructs Encoding Neublastin and Heterologous Signal Sequences**

25 Biological activity was assessed using a kinase receptor activation ELISA (KIRA). The method has been previously described (Sadick et al., 1996, *Anal. Biochem.*, 1996, 235(2):207. Briefly, NB41A3-mRL3 cells, an adherent murine neuroblastoma cell line which expresses Ret and GFR $\alpha$ 3, were plated at  $2 \times 10^5$  cells per well in 24-well plates in Dulbecco's modified eagle medium (DMEM), supplemented with 10% fetal bovine serum, and cultured for 18 hours at 37°C and 5% CO<sub>2</sub>.  
30

The cells were washed with PBS, and treated with serial dilutions of neublastin in 0.25 mL of DMEM for 10 minutes at 37°C and 5% CO<sub>2</sub>. Each sample was analyzed in duplicate. The cells were washed with 1 mL of PBS, and lysed for 1 hour at 4°C  
35 with 0.30 mL of 10mM Tris HC1, pH 8.0, 0.5% Nonidet P40, 0.2% sodium deoxy-

cholate, 50mM NaF, 0.1 mM  $\text{Na}_3\text{VO}_4$ , 1mM phenylmethylsulfonyl fluoride while gently rocking the plates. The lysates were further agitated by repeated pipetting and 0.25 mL of sample was transferred to a 96-well ELISA plate that had been coated with 5 $\mu\text{g}/\text{mL}$  of anti-Ret mAb (AA.GE7.3) (Upstate Biotechnology, Waltham, MA) in 50 mM carbonate buffer, pH 9.6 at 4°C for 18 hours and then blocked at room temperature for one hour with block buffer (20 mM Tris HC1 pH 7.5, 150 mM NaCl, 0.1% Tween-20 (TBST) containing 1% normal mouse serum and 3% bovine serum albumin).

After 2 hours of incubation at room temperature, the wells were washed 6 times with TBST. The plate was washed again before addition of 3,3',5,5'-tetramethylbenzidine dihydrochloride. After the color reaction, absorbance values were read at 450 nm from wells treated with lysate or lysis buffer only, and the background-corrected signal was plotted as a function of the concentration of ligand used for stimulation.

A series of dilutions of conditioned medium was tested, and functional neublastin was detected with a profile similar to a previously demonstrated batch of neublastin expressed, purified, and refolded from *E. coli* (Figure 16).

#### **Example 17: Mature Neublastin Expressed with a Heterologous Signal Peptide**

Appropriate oligonucleotides can be produced according to the method described in Example 9, to clone a DNA sequence encoding a mature neublastin (*i.e.* a 113 C terminal fragment of full-length neublastin). A DNA sequence encoding a signal peptide from rat albumin or human growth hormone can be fused to the DNA sequence encoding a mature neublastin polypeptide as described, in Example 10. The DNA sequence can be transfected into a eukaryotic cell, *e.g.*, a CHO cell, to produce a secreted mature neublastin.

All references cited herein are incorporated herein by reference in their entirety. To the extent publications and patents or patent applications incorporated by reference contradict the disclosure contained in the specification, the specification is intended to supercede and/or take precedence over any such contradictory material.

Many modifications and variations of this invention can be made without departing from its spirit and scope, as will be apparent to those skilled in the art. The specific embodiments described herein are offered by way of example only and are not meant to be limiting in any way. It is intended that the specification and examples be  
 5 considered as exemplary only, with a true scope and spirit of the invention being indicated in the claims.

## Claims

1. A method for producing a biologically active Neublastin polypeptide, comprising  
5           culturing a cell comprising an expression vector comprising a nucleic acid  
              comprising a promoter sequence operably linked to a nucleotide sequence  
              encoding a signal peptide and a Neublastin polypeptide, wherein said  
              nucleotide sequence does not encode a Neublastin pro-region.
- 10       2. The method according to claim 1, wherein the signal peptide is a heterologous  
          signal peptide.
3. The method according to claim 1, wherein the signal peptide is a mammalian  
          signal peptide.
- 15       4. The method according to claim 3, wherein the signal peptide is a human signal  
          peptide, a rat signal peptide, a mouse signal peptide, a porcine signal peptide, a  
          simian signal peptide, a canine signal peptide, a feline signal peptide, a bovine  
          signal peptide, or an equine signal peptide.
- 20       5. The method according to any of the preceding claims, wherein the signal peptide  
          is selected from the group consisting of a growth factor signal peptide, a  
          hormone signal peptide, a cytokine signal peptide and an immunoglobulin signal  
          peptide.
- 25       6. The method according to claim 5, wherein the signal peptide is selected from the  
          group consisting of TGF $\beta$  signal peptides, GDF signal peptides, IGF signal  
          peptides, BMP signal peptides, Neurotrophin signal peptides, PDGF signal  
          peptide and EGF signal peptide.
- 30       7. The method according to claim 5, wherein the signal peptide is selected from a  
          hormone signal peptide, said hormone being selected from the group consisting  
          of growth hormone, insulin, ADH, LH, FSH, ACTH, MSH, TSH, T3, T4, and  
          DHEA.

35

8. The method according to claim 5, wherein the signal peptide is an interleukin signal peptide.
9. The method according to claim 5, wherein the signal peptide is selected from the group consisting of neurturin signal peptide, GDNF signal peptide, persephin signal peptide, and NGF signal peptide.
10. The method according to claim 1, wherein the signal peptide is selected from the group consisting of albumin signal peptide, modified albumin signal peptide, and growth hormone signal peptide.
11. The method according to claim 10, wherein the signal peptide is selected from the group consisting of rat albumin signal peptide, modified rat albumin signal peptide, and human growth hormone signal peptide, such as rat albumin signal peptide and human growth hormone signal peptide.
12. The method according to any of the preceding claims, wherein the signal peptide is a synthetic signal peptide, such as a signal peptide comprising SEQ ID NO: 70.
13. The method according to claim 1, wherein the signal peptide is an Immunoglobulin Signal Peptide.
14. The method according to claim 13, wherein the signal peptide is selected from the group consisting of mouse IgSP (SEQ ID NO 4), rat IgSP (SEQ ID NO 6), porcine IgSP (SEQ ID NO 5), simian IgSP (SEQ ID NO 2 or 3), human IgSP (SEQ ID NO 1).
15. The method of claim 13, wherein the IgSP is mouse IgSP (SEQ ID NO 4).
16. The method of claim 13, wherein the IgSP is human IgSP (SEQ ID NO 1).
17. The method according to claim 1, wherein the signal peptide is a native Neublastin signal peptide.

18. The method according to claim 17, wherein the signal peptide is a native human Neublastin signal peptide.
19. The method according to any of the preceding claims, wherein the neublastin polypeptide is selected from the group consisting of mature NBN selected from Neublastin having a sequence identified as amino acids 1-140 of SEQ ID No 10, or amino acids 1-144 of SEQ ID No 11 or 12, SEQ ID No 13, 14, 15, 16, 17 or 18, N-terminally truncated NBN, mutated NBN, or mutated and N-truncated NBN.
20. The method of claim 19, wherein the neublastin polypeptide is a mature NBN selected from the group consisting of neublastin having a sequence identified by SEQ ID No 13, 14, 15, 16, 16, 17, or 18).
21. The method of claim 20, wherein the neublastin polypeptide is human mature 113NBN (SEQ ID No 14).
22. The method according to any of the preceding claims 1-19, wherein the neublastin polypeptide is selected from the group consisting of the 116 C-terminal amino acids of human neublastin, the 115 C-terminal amino acids of human neublastin, the 114 C-terminal amino acids of human neublastin, the 113 C-terminal amino acids of human neublastin, the 112 C-terminal amino acids of human neublastin, the 111 C-terminal amino acids of human neublastin, the 110 C-terminal amino acids of human neublastin, the 109 C-terminal amino acids of human neublastin, the 108 C-terminal amino acids of human neublastin, the 107 C-terminal amino acids of human neublastin, the 106 C-terminal amino acids of human neublastin, the 105 C-terminal amino acids of human neublastin, the 104 C-terminal amino acids of human neublastin, the 103 C-terminal amino acids of human neublastin, the 102 C-terminal amino acids of human neublastin, the 101 C-terminal amino acids of human neublastin, the 100 C-terminal amino acids of human neublastin, and the 99 C-terminal amino acids of human neublastin,
23. The method of claim 1, wherein the neublastin polypeptide is selected from the group consisting of N-terminally truncated Neublastin with the 106, 104, 102 or 99 C-terminal amino acids of SEQ ID NO 10.

24. The method according to claim 1, wherein the neublastin polypeptide is selected from the group consisting of the 116 C-terminal amino acids of human neublastin, the 113 C-terminal amino acids of human neublastin, the 104 C-terminal amino acids of human neublastin, and the 116 C-terminal amino acids of human neublastin.
25. The method of claim 1, wherein the N-terminally truncated Neublastin has the amino acid sequence of SEQ ID No 19.
26. The method of claim 1, wherein the N-terminally truncated Neublastin contains the 99 amino acids of SEQ ID NO 20.
27. The method of claim 1, wherein the neublastin polypeptide comprises an amino acid sequence derived from amino acids 8-113 of SEQ ID No. 14, wherein the variant neublastin polypeptide includes one or more of the amino acid substitutions selected from the group consisting of: an amino acid other than arginine at position 14 in the amino acid sequence of said variant polypeptide, an amino acid other than arginine at position 39 in the amino acid sequence of said variant polypeptide, an amino acid other than arginine at position 68 of said variant polypeptide, and an amino acid other than asparagine at position 95 of said variant polypeptide, wherein the positions of said amino acids are numbered in accordance with the polypeptide sequence of SEQ ID No. 14.
28. The method of claim 27, wherein said substitution at position 14, 39, or 68 is lysine.
29. The method according to any of the preceding claims, wherein the vector is a plasmid.
30. The method according to any of the preceding claim 1-28, wherein the vector is a virus vector.
31. The method according to any of the preceding claims, wherein the vector is a mammalian expression vector.

32. The method according to claim 30, wherein the vector is a replication-defective lentivirus particle.
- 5 33. The method according to claim 32, wherein said vector particle being produced from a lentiviral vector comprising a 5' lentiviral LTR, a tRNA binding site, a packaging signal, a promoter operably linked to a polynucleotide signal encoding said signal peptide and said neublastin peptide, an origin of second strand DNA synthesis and a 3' lentiviral LTR.
- 10 34. The method according to claim 30, wherein the vector is selected from the group consisting of retrovirus, such as HIV, SIV, FIV, EIAV, AAV, adenovirus, herpes virus, and MoMLV.
- 15 35. The method according to any of the preceding claims, wherein the promoter is selected from the group consisting of: ubiquitin promoter, CMV promoter, JeT promoter, SV40 promoter, Elongation Factor 1 alpha promoter (EF1-alpha), chick beta-actin, PGK, and MT-1.
- 20 36. The method according to claim 34, wherein the promoter is an inducible/repressible promoter, such as: Tet-On, Tet-Off, Rapamycin-inducible promoter, Mx1, and RU486.
- 25 37. The method according to any of the preceding claims, wherein the cell is a mammalian host cell.
38. The method of claim 37, wherein said mammal is selected from the group consisting of rodent, rabbit, dog, cat, pig, monkey, human being.
- 30 39. The method of claim 37, said cell being selected from the group consisting of CHO, HEK293, COS, PC12, HiB5, RN33b, neuronal cells, foetal cells, ARPE-19, immortalised fibroblast cells, C2C12, HeLa, HepG2, Retinal Pigment Epithelial (RPE) cells, striatal cells, neurons, astrocytes, interneurons.
- 35 40. The method according to claim 39, wherein the cell is a CHO cell.

- 5 41. A nucleic acid comprising a polynucleotide sequence encoding a signal peptide and a neublastin polypeptide, wherein said polynucleotide sequence does not encode a neublastin pro-region, said signal peptide and said neublastin peptide being as defined in any of claims 1-40.
- 10 42. The nucleic acid according to claim 41, comprising a) the nucleotide sequence of SEQ ID NO: 64, 66, or 68, or b) a nucleotide sequence encoding the polypeptides of SEQ ID NO: 65, 67, or 69.
43. The nucleic acid according to claim 41 or 42, wherein the nucleotide sequence has been optimised for expression in a mammalian host.
- 15 44. An expression vector comprising the nucleic acid as defined in any of claims 41-43.
- 20 45. A pharmaceutical composition comprising the vector as defined in claim 44 and one or more of pharmaceutically acceptable adjuvants, excipients, carriers and/or diluents.
46. An isolated host cell transduced or transfected with the vector as defined in claim 44.
- 25 47. The cell according to claim 46, wherein the cell is a mammalian cell.
48. The mammalian cell according to claim 47, wherein the cell is capable of secreting Neublastin or a functional equivalent thereof in amounts in excess of 500 ng/10<sup>6</sup> cells/24 hours.
- 30 49. The mammalian cell according to claim 47, being selected from the group consisting of CHO, HEK293 COS, PC12, HiB5, RN33b, immortalised fibroblast cells, C2C12, HeLa, HepG2, RPE cell lines, and ARPE-19 cells.
- 35 50. The mammalian cell according to claim 48, being selected from the group consisting of CHO, HEK293, COS, and ARPE-19.

51. The mammalian cell according to claim 47, being selected from the group consisting of RPE cells, neuronal cells, neuronal precursor cells, stem cells, and foetal cells.
52. The mammalian cell according to claim 47, being attached to a support matrix.
53. A packaging cell line capable of producing an infective vector particle, said vector particle comprising a retrovirally derived genome comprising a 5' retroviral LTR, a tRNA binding site, a packaging signal, a promoter operably linked to a polynucleotide sequence encoding a signal peptide and a neublastin polypeptide, wherein said nucleotide sequence does not encode a neublastin pro-region and said signal peptide and neublastin peptide being as defined in any of claims 1-40, and an origin of second strand DNA synthesis, and a 3' retroviral LTR.
54. The packaging cell line according to claim 53, wherein the vector particle is replication defective.
55. The packaging cell line according to claim 53, wherein the genome is lentivirally derived and the LTRs are lentiviral.
56. A transgenic non-human mammal comprising at least one cell being transduced or transfected with the vector as defined in claim 44.
57. The mammal of claim 56, wherein the at least one transduced or transfected cell comprises the genome of the mammal.
58. An implantable cell culture device, the device comprising:
- i. a semipermeable membrane permitting the diffusion of a growth factor therethrough; and
  - ii. at least one isolated host cell as defined in claim 46.
59. The device of claim 56, wherein the semipermeable membrane is immunoisulatory.

60. The device of claim 56, wherein the semipermeable membrane is microporous.
61. The device of claim 56, wherein the device further comprises a matrix disposed  
5 within the semipermeable membrane.
62. The device of claim 56, wherein the device further comprises a tether anchor.
63. Use of the vector according to claim 44 or the device according to any of the  
10 claims 56 to 60 as a medicament.
64. Use of the vector according to claim 44 for the preparation of a medicament for  
the treatment of a nervous system disorder.
- 15 65. The use of claim 64, wherein the nervous system disorder is selected from the  
group consisting of peripheral neuropathy including neuropathic pain, spinal cord  
injury, spinal root avulsion, tic doloureux, and causalgia.
66. The use according to claim 63, wherein the medicament is for the treatment of  
20 an eye disease, such as corneal wounds and ulcers, and retinopathies.
67. Use of the vector according to claim 44 for the preparation of a medicament for  
the treatment of a CNS disorder.
- 25 68. The use according to claim 67, wherein the CNS disorder is a  
neurodegenerative disease.
69. The use of claim 64, wherein the neurodegenerative disease is peripheral  
neuropathy including neuropathic pain.  
30
70. A method of treating a nervous system disease, said method comprising  
administering to an individual in need thereof:
- i. a therapeutically effective amount of the vector as defined in  
claim 44, or

- ii. a therapeutically effective amount of a pharmaceutical composition as defined in claim 45.

- 5 71. The method of claim 70, wherein the vector is administered intramuscularly, subcutaneously, or intraperitoneally.
72. The method of claim 70, wherein the vector or composition is administered to an area of the body involved in transmission of pain sensation.
- 10 73. The method of claim 70, wherein the vector or composition is administered intrathecally or to the spinal cord.
74. The method of claim 70, wherein the vector is administered to the brain, including the parenchyma, and the ventricles.
- 15 75. The method of claim 70, wherein the vector is administered into the eye, including the vitreous, subretinal space, and sub-tenar capsule.
- 20 76. The method of claim 70, wherein the nervous system disease is selected from the group consisting of peripheral neuropathy including neuropathic pain, spinal cord injury, spinal root avulsion, tic doloreaux, causalgia, corneal wounds, and retinopathies.
- 25 77. A method of treating a nervous system disease, said method comprising transplanting to an individual in need thereof a therapeutically effective amount of the cells of claim 46.
78. The method of claim 77, wherein transplantation comprises an autologous transplant, an allogeneic transplant or a xenogeneic transplant.
- 30 79. The method of claim 77, wherein said cells are administered intrathecally or to the spinal cord.
- 35 80. The method of claim 77, wherein the cells are administered to the brain, including the parenchyma, and the ventricles.

81. The method of claim 77, wherein the cells are administered into the eye, including the vitreous, subretinal space, and sub-tenar capsule.
- 5 82. The method of claim 77, wherein the nervous system disease is selected from the group consisting of peripheral neuropathy including neuropathic pain, spinal cord injury, spinal root avulsion, tic doloreaux, causalgia, corneal wounds, and retinopathies.
- 10 83. A method of treating a nervous system disease, said method comprising transplanting to an individual in need thereof an implantable device as defined in claim 56.
- 15 84. The method of claim 77, wherein transplantation comprises an autologous transplant, an allogeneic transplant or a xenogeneic transplant.
85. The method of claim 83, wherein said device is implanted intrathecally or to the spinal cord.
- 20 86. The method of claim 83, wherein the device is implanted administered to the brain, including the parenchyma, and the ventricles.
87. The method of claim 83, wherein the device is implanted administered into the eye, including the vitreous, subretinal space, and sub-tenar capsule.
- 25 88. The method of claim 83, wherein the nervous system disease is selected from the group consisting of peripheral neuropathy including neuropathic pain, spinal cord injury, spinal root avulsion, tic doloreaux, causalgia, corneal wounds, and retinopathies.
- 30 89. The method according to any of the claims 72-80, for the treatment of neuropathic pain comprising administering to an individual in need thereof a therapeutically effective amount of a vector as defined in claim 44, or a composition of cells as defined in any of claims 46-50, or a cell device as defined in 56.

90. A neublastin polypeptide comprising a signal peptide and a neublastin polypeptide, wherein the polypeptide lacks a neublastin pro-region.
- 5 91. The polypeptide according to claim 90, wherein the neublastin polypeptide is fused to the signal peptide.
92. The polypeptide according to claim 91, wherein the signal peptide is linked through its C-terminal to the N-terminal of the neublastin polypeptide through a peptide bond.
- 10 93. The polypeptide according to any of the preceding claims 90-92, wherein the signal peptide is a heterologous signal peptide.
94. The polypeptide according to any of the preceding claims 90-93, wherein the  
15 signal peptide is as defined in any of the claims 1-40.
95. The polypeptide according to claim 94, wherein the signal peptide is selected from the group of signal peptides selected from native rat albumin signal peptide, modified rat albumin signal peptide, and human growth hormone signal  
20 peptide.
96. The polypeptide according to any of the preceding claims 90-94, wherein the signal peptide is a Neublastin signal peptide.
- 25 97. The polypeptide according to any of the preceding claims 90-94, wherein the signal peptide is an IgSP.

ance Notes on Codes and Abbreviations" appearing at the begin-  
ning of each regular issue of the PCT Gazette.

(54) Title: IMPROVED SECRETION OF NEUBLASTIN

(57) Abstract: The present invention concerns methods and compositions for producing a neublastin polypeptide as well as local delivery of neublastin to specific regions of the nervous system including the central nervous system and the eye for example by gene therapy. The biologically active neublastin polypeptide is produced from a construct not encoding naturally occurring neublastin pro-region, i.e. a construct comprising a nucleic acid with a promoter sequence operably linked to a nucleotide sequence encoding a signal peptide and a neublastin polypeptide, wherein said nucleotide sequence does not encode a neublastin pro-region.

☒ Patent family members are listed in annex.

### \* Special categories of cited documents :

- \*A\* document defining the general state of the art which is not considered to be of particular relevance
- \*E\* earlier document but published on or after the international filing date
- \*L\* document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- \*O\* document referring to an oral disclosure, use, exhibition or other means
- \*P\* document published prior to the international filing date but later than the priority date claimed

- \*T\* later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
- \*X\* document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
- \*Y\* document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.
- \*G\* document member of the same patent family

## INTERNATIONAL SEARCH REPORT

International application No.  
PCT/DK2004/000411

### Box II Observations where certain claims were found unsearchable (Continuation of item 2 of first sheet)

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☒ Claims Nos.:  
because they relate to subject matter not required to be searched by this Authority, namely:  
  
Although claims 70-89 are directed to a method of treatment of the human/animal body, the search has been carried out and based on the alleged effects of the compound/composition.
2. ☐ Claims Nos.:  
because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:
3. ☐ Claims Nos.:  
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

### Box III Observations where unity of invention is lacking (Continuation of item 3 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

1. ☐ As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

#### Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest.
- ☐ No protest accompanied the payment of additional search fees.
